

A MONOGRAPH  
OF THE GENUS  
GERANIUM L.  
(GERANIACEAE)

CARLOS AEDO  
Real Jardín Botánico  
CSIC

This long awaited monograph deals with the fascinating group of plants known as geraniums or cranesbills. It is restricted to the plants covered by the scientific name *Geranium*, but does not include those plants known in English as "geranium" which botanists have transferred to the genus *Pelargonium*. The book is the result of 28 years of research by the author. It is lavishly illustrated with maps, line drawings and photographs.

There is a gap in the available botanical literature covering the geraniums. The last monographic treatment by Reinhard Knuth appeared in 1912. In the intervening years, much taxonomic information has been accumulated, rendering this massive and comprehensive work out of date. There have been many new species discoveries and much research has been conducted for revisional works. All these changes have caused much confusion to the outsider, making the need for a comprehensive monograph even more pressing.

For each of the 307 species covered in this book, complete synonymy and detailed description is given, as well as its distribution, relationships, variability and taxonomic history are discussed. Each species is provided with a map showing its known distribution based on specimens examined by the author, and is illustrated with line drawings and, if available, with colour photographs based on reliable specimens. Some introductory sections explain in detail the morphological structure of these plants, chromosome numbers, breeding system, phytochemistry, distribution, habitats and relationships. For practical reasons and to facilitate the identification of the species, four identification keys have been prepared that cover respectively North and Central America, South America, the Pacific area and the Old World species. This book will be of value to botanists, but also for specialists hobbyists and to anyone fascinated by these plants.

A MONOGRAPH  
OF THE GENUS GERANIUM L.  
(GERANIACEAE)

[Stearn 1992: 22]

## INTRODUCTION

*Geranium* L., with 307 species, is the largest genus of the Geraniaceae, a family that according to Stevens (2001), also contains the genera *Pelargonium* L'Hér. (280 species), *Erodium* L'Hér. (80 species, including *California* Aldasoro & al.), *Monsonia* L. (40 species, including *Sarcocaulon* Sweet) and *Hypseocharis* Remy (2 species; Lozada-Gobilard & al. 2020). *Hypseocharis*, however, differs from the other genera by its estipulate leaves, capitate stigma, ovaries with many ovules per loculus, and unbeaked fruits. This set of characters may support assignment to a monotypic family sister of the Geraniaceae core (Aedo 2012, Palazzesi & al. 2012). Retaining *Hypseocharis* would result in the Geraniaceae losing the main characters (stipulate leaves, style with 3-5 stigmatic branches, one or two ovules per loculus, beaked fruits) that define the family. Regarding the generic division of the family, the synonymization of *California*, and especially those of *Sarcocaulon* seems controversial (Albers 1996, Dreyer & al. 1997, Moffett 1979, 1997).

After the segregation of *Erodium*, *Monsonia*, *Pelargonium* (see *Historical overview*) from *Geranium*, the circumscription of the genus has been stable throughout its recent history. Three attempts to separate some species into independent genera have not been followed by most of the authors: *Robertium* to accommodate some species of sect. *Ruberta* (Picard 1837), *Neurophyllodes* to accommodate the species of sect. *Neurophyllodes* (Degener & Greenwell 1937), and *Geraniopsis* to accommodate two species of sect. *Trilophia* (Chrtek 1968).

The genus *Geranium* is easily differentiated from the other genera of the family by its usually actinomorphic flowers with five free petals, without hypanthium nor nectariferous tube, and with ten free stamens arranged in two whorls, very rarely the outer lacking the anthers. *Geranium* is distributed throughout most of the world except in lowland tropical areas, but it has diversified more in certain regions. The mountains around the Mediterranean Basin, the Caucasus and the Himalayas constitute some of these regions. Regarding the Old World, also South Africa and the mountains of New Guinea are very rich in endemic species. In the New World, the two areas particularly diverse in species are Mexico and adjacent regions of western U.S.A., and the north of the Andes, from Venezuela to northern Peru.

Knuth's (1912) worldwide monograph of *Geranium* was the most complete treatment of the genus during several decades, and a good starting point for an overview of the genus. This author accepted 269 species plus 72 more species in subsequent papers (Knuth 1913, 1915, 1916, 1922, 1923, 1930a, 1930b, 1931, 1933, 1934, 1936, 1937a, 1937b, 1938, 1939). This impressive monograph causes even more astonishment when we consider that it covers the whole Geraniaceae, in a broad sense, including small related families.

According to Melchior (1957: 185), Reinhard Knuth received his doctorate in 1902 with the dissertation entitled *Über die geographische Verbreitung und die Anpassungs-*

*scheinungen der Gattung Geranium im Verhältnis zu ihrer systematischen Gliederung* (Knuth 1903, 1904). He collaborated with F. Pax in the monograph treating Primulaceae published in 1905 in the Engler's *Pflanzenreich*. Subsequently he wrote monographs on Geraniaceae for the same series directed by A. Engler. The main work seems to have been carried out in a relatively short period, perhaps less than ten years, taking into account that his first taxonomic publication on the genus is from 1904 (Knuth 1904). This monograph should be seen in the context of its time, in which many areas were still unexplored or undercollected and loans between herbaria were not routinely done. This resulted, as an unavoidable consequence, in the scarcity of material for preparing full descriptions and keys, and for obtaining detailed distributions of the species. These limitations led to the description of some species that are now seen as synonyms. This however does not diminish the value of Knuth's work (Fig. 1).

Among the relevant contributions after Knuth's monograph, many floras can be mentioned. The list is, however, lengthy and it would be difficult to do justice to all the efforts of the authors of these works. One relevant example would be *Flora of the U.R.S.S.* (Bobrov 1949), that covers more than 22 million km<sup>2</sup>, and presents a valuable taxonomic treatment of *Geranium* (55 species). Other important works that cover areas poorly known are those of Moore (1943) for species of Mexico and Central America, Jones & Jones (1943) for United States and Canada, Carolin (1965) for the southwestern Pacific area, Veldkamp & Moerman (1978) for the Malesian species, and Hilliard & Burtt (1985) for South African species.

A considerable advance in the knowledge of *Geranium* occurred with the works of P. Yeo, some focused on classification and others that studied various groups in particular. Among works on classification, it should be mentioned the new proposal for an infrageneric classification by Yeo

Fig. 1. Reinhard Knuth's handwritten label used to identify the plants studied in his monograph. Specimen preserved in the herbarium of University of Zurich (Z-000064950).

(1982, 1984, 1990), inspired in Tokarski (1972), and among group studies Yeo (1970, 1973a, 1973b, 1975, 1983, 1992, 2003, 2004).

The difficulty of preparing monographic treatments of large genera is well known (Frodin 2004) and applies to medium-sized genera as *Geranium* as well. The initial strategy for preparing an updated monograph of the genus was to review sections or subgenera that were well-characterized morphologically (Aedo 1996, 2001a, 2003, 2017b; Aedo & al. 1998, 2002, 2003, 2005a, 2005b, 2007, 2009, 2016; Aedo & Estrella 2006). However, these well-defined subgroups cover only a minor part of the genus. Consequently, to move forward, a change of approach was needed. For this reason the study of well-defined groups was combined with the study of species from little or poorly known areas. The species of China (Xu & Aedo 2008), the New World (Aedo 2012), the Iberian Peninsula (Aedo 2015), and the Pacific area (Aedo 2017a), have been revised in this way. Despite all this work, a part of the species of Eurasia and Africa requiring detailed study still remains. They are now here presented with the remaining of the genus.

For the present monograph, these previous accounts were amended as necessary. The descriptions were harmonized as much as possible, but in some cases it was not possible to complete some characters of species because the loans had been returned. The nomenclature was revisited and some new types were found. The delimitation of the species, as well as keys and distribution ranges, have sometimes been refined in light of the study of new collections.

## HISTORICAL OVERVIEW

In early manuscripts about plants of Western culture, geraniums are occasionally mentioned. Dioscorides in his *De Materia Medica*, written between AD 50 and 70, provided a reference and a drawing (3.116) of a species of this genus difficult to identify but probably *Geranium rotundifolium* or *G. molle* (Estrella 2006). Pliny the Elder in his *Historiae Naturalis* (AD 77) refers to what seem to be two geraniums. He describes the first as a herb similar to hemlock, with smaller leaves and shorter stem and bearing at the top of the branches heads of cranes, which strongly suggest that it is an *Erodium*. The second plant is described as having leaves like those of anemone and a round root like an apple, which could indicate that it is *G. tuberosum* or other species of the section *Tuberosa* (Huerta 1629: 415; Jones 1966: 344). According to Sharples & Minter (1983) there is, however, some controversy about the use of the term geranium in the botanical writings by Theophrastus and Pliny the Elder.

After the medieval period which contributed little to the botanical knowledge from the Greek and Latin classics, a new current developed in central Europe. The herbalist Leonhart Fuchs is one of its main representatives. Fuchs (1542: 204-211) provided six drawings of European *Geranium*, some identifiable as *G. robertianum* and *G. sylvaticum*, one *Erodium* sp. and some *Geranium* sp. Unfortunately, these authors did not conserve the plants in herbaria and therefore the identification of their species cannot be confirmed.

It is more difficult to find ancient references outside the scope of Western culture. An interesting case are the manuscripts of Francisco Hernández who traveled through Mexico between 1572 to 1577 and collected information on the natural history of Mexican pre-Hispanic cultures. His manuscripts were published abbreviately from 1629 by Nardi Antonio Reccho in different editions. In one edition two drawings of Mexican taxa of *Geranium* are found but they cannot be assigned to any known species (Hernández 1649: 293). No herbarium testimonies are known to clarify the identity of these species.

In the Cinquecento the technique of pressing plants and preserving them in bound volumes was developed in northern Italy. Over time this gave rise to herbaria as we know them today. The oldest known pressed specimens of *Geranium* date from this time. According to Chiovenda (1928: 130), specimens of *Geranium nodosum* and *G. san-*

Fig. 2. Specimens of *Geranium nodosum* (FI-060876) and *G. sanguineum* (FI-060877) from Anonimo Toscano herbarium (formerly attributed to Michelle Merini), dated ca. 1544, and kept at the *Museo di Storia Naturale*, University of Florence (FI) [photo: the staff of the herbarium].

*guineum* (Fig. 2) are found in the herbarium attributed to Michelle Merini. A recent study suggests that there is insufficient evidence to attribute this herbarium to Merini and that it is more appropriate to consider it anonymous (Cristofolini & Nepi 2021). This herbarium is kept at the *Museo di Storia Naturale*, University of Florence (FI) and dated ca. 1544. It seems that it was compiled with plants cultivated in the Pisa botanical garden. They are the oldest known herbarium specimens of *Geranium*. Since that time it is referred to as the Cibo herbarium, attributed to Francesco Petrollini. It contains thirteen specimens of *Geranium* (*G. dissectum*, *G. lucidum*, *G. macrorrhizum*, *G. nodosum*, *G. rotundifolium*, and *G. sanguineum*) (Fig. 3). This herbarium, kept in the *Biblioteca Angelica*, Rome, is dated from 1550-53 (Celani 1902; Stefanaki & al. 2019). The specimens were probably collected in Italy.

According to Caruel (1858: 114-115), in the herbarium of Andrea Cesalpino specimens of *G. columbinum*, *G. dissectum*, *G. nodosum*, *G. robertianum* and *G. sylvaticum* are preserved (Fig. 4). The specimens, probably from northern Italy, are organized following a new system of classification based on Aristotle and Theophrastus, later published by Cesalpino (1583) as *De Plantis libri XVI*. The geraniums are mentioned on the pages 558-559. This herbarium is kept at the *Museo di Storia Naturale*, University of Florence (FI) and dated from 1563 (Nepi 2007; Nepi & Gusmeroli 2008).

From this time on, the information about the plants of Europe and the Mediterranean Basin is increased with the appearance of numerous books and, progressively more collections preserved in herbaria. Caspar Bauhin (1623: 317-319) in his *Pinax Theatri Botanici*, mentions 26 geraniums, with a complete synonymy, giving his work an innovative character for its time. He describes different species of *Geranium* and *Erodium* which are widely distributed Europe that can be easily identified from the herbarium vouchers kept at the University of Basel, Switzerland (BAS).

John Ray (1688: 1055-1063) in his *Historia plantarum* recognized 40 species of *Geranium* (in a broad sense) that were expanded considerably in a supplement (Ray 1704: 511-515). In this work he introduces dichotomous keys to identify the genera. His herbarium vouchers are kept at The Natural History Museum, London (BM).

Tournefort (1700: 266-270) in his *Institutiones rei herbariae* accepts *Geranium* as a genus. The effort of this author had great influence on consolidation and consistent definition of the genera. The number of species accepted for the genus increased to 81 (including *Geranium* and *Erodium*), mostly Europeans but also from the Middle East where Tournefort himself carried out an expedition. His herbarium, kept at the *Muséum National d'Histoire Naturelle*, Paris (P-TRF), can help to clarify the complex polynomial nomenclature that Tournefort applied to his species.

The binomials that were used in an irregular way by previous authors were consolidated with the Linnaeus's *Species plantarum*, which is accepted as the starting point

of modern nomenclature. Linnaeus's (1753: 676) circumscription of *Geranium* included *Erodium*, and *Pelargonium*, as the previous authors did. However, *Geranium* s.str. was recognized implicitly by Linnaeus as the group defined by "Staminibus decem fertilibus", in which he included fifteen species still accepted in *Geranium* s.str. today. Most of Linnaeus's geraniums are European (except those now transferred to *Pelargonium*) but there are two American and one Siberian. The former are *G. carolinianum* and *G. maculatum* that Linnaeus cited through Gronovius's *Flora virginica* (1743: 78), which was based on John Clayton's collections. Among the Clayton specimens at BM, only the original material of *G. carolinianum* is extant. It is the earliest collection of the genus in North America and probably dates from ca. 1735 (Reveal & Pringle 1993: 161).

Cavanilles (1787) published an important revision of the Geraniaceae, which listed 127 species, following Linnaeus's generic concept of *Geranium* and accepting the new genus *Monsonia* (Linnaeus 1767). Cavanilles had access to important extra-European collections in the Paris herbarium, which allowed him to work with the South African geraniums (now under *Pelargonium*). In his monograph he

Fig. 3. Specimen of *Geranium nodosum* from Cibo herbarium, attributed to Francesco Petrollini, prepared in 1550-53, and kept at the *Biblioteca Angelica*, Rome [Erbario B 129/498].

includes 31 species of *Geranium* s.str., most still European, although he described the first species from South America: his *G. sessiliflorum* was based on a collection by Philibert Commerson and Jeanne Baret, the French naturalists, who accompanied Louis Antoine de Bougainville on his voyage of circumnavigation in 1766-1769. There are, however, older references to *Geranium* from South America. For example, Feuillée (1725: 21, pl. 16) reported a species of *Geranium* from the Chilean coast in ca. 1709. No herbarium material was found, but the drawing shows a perennial species that probably belongs to the *Solanderi* Group.

In 1792 L'Héritier published the drawings of his *Geraniologia*, but the text was never published conventionally (Britten & Woodward 1905: 271; Guittonneau 1967: 42-45). Many of L'Héritier's names, including *Erodium* and *Pelargonium*, had been validated by Aiton (1789: 414, 417). L'Héritier's delimitation of the genus *Geranium* agrees with the current circumscription and has been widely accepted until today. The publications by Andrews (1805-06) and Dumont

de Courset (1802, 1805, 1811) do not recognize L'Héritier's genera but they had little or no influence on *Geranium* s.str.

For many years the most remote regions of the world remained scarcely known from the floristic point of view. For instance, Carl Thunberg collected in Japan in 1775-1776 and mentioned only one species of *Geranium*, "*Geranium palustre*" from Nagasaki, which is probably one of the first collections of the genus in the area (Thunberg 1784: 268). No specimen of *Geranium* is kept in the Thunberg herbarium (UPS) (M. Hjertson, *in litt.*), but a specimen labeled by Thunberg is found in the Burman herbarium at G. This plant corresponds to *G. thunbergii*, a name proposed by Siebold & Zuccarini (1845: 28) and later validated by Lindley & Paxton (1851: 186).

The earliest known collection of a Hawaiian geranium was made in 1793 by Archibald Menzies, the surgeon and naturalist under Captain Vancouver on the HMS Discovery (Pax & al. 1997: 72). His finding was described by Hooker as *G. cuneatum* (1837). There were no further important additions to the knowledge of Hawaiian geraniums until the United States Exploring Expedition under the command of Commodore C. Wilkes in 1840. From the plants collected at that time by William Brackenridge and others, Gray (1854) published seven new geraniums, five of them accepted today at specific or subspecific level.

The geraniums of tropical southeastern Asia remained unknown until Zollinger (1845: 585) published his *G. ardjunense* as a new species, based on a collection that he made in Java. The higher mountains of New Guinea, which harbor most species of the genus on the island, remained unexplored and their species undescribed until the end of the twentieth century. The only species from the region published in the intervening period were two species from New Guinea published by Ridley (1916), based on collections by Cecil Kloss.

Joseph Banks and Daniel Solander arrived in New Zealand in October of 1769 accompanying Captain Cook on his first voyage on the HMS Endeavour (Adams 1986). They collected *G. potentilloides* and *G. retrorsum*, later described by De Candolle (1824), who attributed the collections to Banks only. The next species described from the region was *G. brevicaule*, which was based on a collection from Tasmania made by Ronald Gunn (Hooker 1834: 252).

In his worldwide synthesis of Geraniaceae, De Candolle (1824) agreed with L'Héritier's concept of the genus and recognized 66 species of *Geranium*, including species collected in the Andes by Alexander von Humboldt and Aimé Bonpland, by Martín Sessé and José Mociño in Mexico, by Nathaniel Wallich in the Himalayas, by Christian von Steven in the Caucasus and by several collectors in Siberia. De Candolle (1824) arranged an infrageneric proto-classification, partially inspired by Cavanilles (1787, without page number: *Geraniorum tabula analytica*), grouped the species in three clades: *Perennia*, *pedunculis 1-floris*, *Perennia*, *pedunculis bifloris*, and *Annua*, *pedunculis bifloris*. Bentham & Hooker (1862) proposed a wide delimitation of the Ge-

Fig. 4. Specimens of *Geranium dissectum*, *G. nodosum* and *G. sylvaticum* [plus *Erodium* sp.] from Andrea Cesalpino herbarium, prepared in 1563, and kept at the Museo di Storia Naturale, University of Florence (FI) [photo: the staff of the herbarium].

raniaceae, but maintained the narrow circumscription of *Geranium* and attributed to the genus about 100 species.

Dumortier (1827) accepted a division of the genus in three sections which only partially agreed with De Candolle (1824) and is restricted to Belgian species. Koch (1835) also proposed three sections, agreeing in part with those of previously mentioned authors but expanding the geographic area and the number of species. Picard (1837), Boissier (1867), Rouy (1897), Bubani (1901) and Fiori & Paoletti (1901) also organize the species in their respective work areas into infrageneric categories. It is necessary, however, to wait for Knuth's (1912) monograph to find a proposal for a worldwide infrageneric classification.

After De Candolle's synthesis, a large number of new species were published, generally linked to the exploration of little-known areas. These were evaluated in Knuth's (1912) monograph. More recent relevant treatments are noted in the Introduction.

## MATERIAL AND METHODS

This revision is based on 25,953 herbarium specimens from the following herbaria: A, AAU, ABS, AD, AK, ALA, ANG, APP, ARAN, ARIZ, ATH, B, BAF, BC, BCN, BEOU, BH, BIRM, BISH, BM, BO, BOL, BOLV, BP, BR, BRIT, BRNM, BRNU, BRSL, BUCA, C, CAL, CAN, CANB, CAR, CAS, CDBI, CGE, CHR, CL, CLU, CM, COFC, COI, COL, COLO, CONC, CORD, CTES, DAO, DBN, DUKE, E, ENCB, ERE, F, FI, FT, G, GA, GB, GDA, GH, GOET, GRA, GRM, GZU, H, HA, HAL, HAO, HBG, HBIL, HGI, HO, HUA, HUB, HUJ, HULE, HVR, IBF, IBSC, ICEL, IEB, ILL, INB, IND, ISC, ISTE, ISTO, JACA, JBAG, JBSD, JE, JEPS, K, KANU, KASH, KE, KR, KRA, KUH, KUN, KUS, KW, KY, KYO, L, LD, LE, LEB, LIL, LINN, LISE, LISI, LIV, LOJA, LOU, LP, LPA, LPB, LUX, LW, LWG, LY, LZ, M, MA, MACB, MADJ, MADM, MAF, MEL, MER, MERL, MEXU, MFU, MICH, MIN, MO, MONTU, MOR, MPU, MSB, MSC, MSTR, MU, MUB, MW, NA, NAP, NBG, NDG, NEB, NEU, NHMC, NMC, NMW, NSK, NSW, NU, NY, O, OBG, OBI, OKL, ORE, OSC, OXF, P, PACA, PAL, PAVL, PE, PERTH, PH, PO, PORT, PR, PRC, PRE, QCA, QFA, QPLS, R, RB, RENO, RO, RSA, S, SALA, SAPS, SBBG, SD, SEV, SGO, SI, SIB, SKO, SLBI, SOM, SP, SS, STU, SYD, SZ, TAA, TAI, TAUF, TBI, TENN, TEX, TFC, TI, TK, TNS, TUB, U, UB, UC, UNM, UPA, UPS, US, USM, V, VEN, VLA, VT, W, WA, WAG, WELT, WIS, WRSL, WTU, WU, WVA, XAL, Z, ZT, and the private herbaria of J. Bouchard, G.G. Guittonneau, S. Halloy and G.H. Parent.

The revision includes 652 herbarium specimens of *Geranium* belonging to 110 species and assessments of natural populations obtained by the author in field trips to Argentina, Bolivia, Brazil, Chile, Costa Rica, Ecuador, Nicaragua, Peru, the United States, and Venezuela in the New World and to Armenia, Austria, Bulgaria, Cyprus, Equatorial Guinea, France, Germany, Great Britain, Greece, Italy, Morocco, Norway, Portugal, Romania, Slovenia, South Africa, Spain, Switzerland, Tunisia, and Turkey in the Old World.

The account presented in the *Taxonomy* includes a comprehensive synonymy. All names have been verified in their original publication. The names that share the same type are indicated in the same paragraph, ordered by publication date. In each paragraph there is a heading named "type locality" in which the geographical information of the protologue is literally transcribed. These data are followed by the type, giving the information that comes from the label in a standard way, and supplying the geographic or collector information that may be missing. The disposition of names for which no type material was available is based on the opinions of previous authors or in a few cases, on the original description. Invalidly published names and names that could not be fixed with certainty are listed under *Miscellaneous doubtful and not validly published names* (see also Appendix 2 for names which now belong to other genera).

One hundred nine (109) characters, 72 qualitative traits, and 32 quantitative traits, as well as five ratios were scored for the description of the species. At least 15 specimens were scored for each species, if available. Quantitative characters were assessed with a Mitutoyo CD-15CD digital caliper (Mitutoyo, Kawasaki, Japan). The most frequent values are percentiles (between the 25th and 75th percentiles), are shown without brackets, and the extreme values are enclosed in brackets. All measurements were taken from herbarium specimens. The line drawings of leaf laminas and petals show the adaxial surface, and drawings of the sepals show their abaxial surface, unless stated otherwise. In the descriptions and key, the length of the sepal does not include the length of the mucro. The use of the term "Leaves" refers to the lamina of the leaf unless stated otherwise. Similarly, the description of the leaf segments refers to the middle segment unless otherwise indicated.

Under the heading *Representative specimens examined* a selection of specimens representative of the distribution of the species is indicated. When the species is rare or few specimens have been studied, all of them are listed under the *Additional specimens examined* section. In no case are the type specimens repeated, as they have already been mentioned together with their corresponding names. The specimen labels have been transcribed in the language in which they were written. Only in those cases written in non-Latin alphabets (Chinese, Japanese, Korean or Russian), have they been transliterated to the Latin alphabet, either to English or to Spanish. For country names, the 1999 edition of *The Times comprehensive Atlas of the World* [Times Books, London] has generally been followed. Changes after that date have been incorporated when considered useful. In the case of the Democratic Republic of the Congo, however, the name of Zaire has been maintained, because it is widely used in the literature and avoids confusing with the neighboring Republic of the Congo.

Each species has been mapped based on the studied specimens. When the specimens lacked geographic coordi-

nates, they have been georeferenced using the *NGA GEOnet Names Server website* and other similar tools. The precision of these georeferencing is logically variable and heterogeneous.

Color photographs were taken by the author unless stated otherwise. For SEM, samples were glued to aluminum stubs, coated with 40-50 nm of gold, and examined with a JEOL-TSM T330A (JEOL USA Inc., Peabody, Massachusetts) SEM at 15 kV.

For practical reasons and to facilitate the identification of the species, four identification keys have been prepared. In these regional keys there is little overlapping, except for some non-native species. Each regional key includes all native species, species non-native but clearly naturalized, and some occasional or adventive species usually based on reliable bibliographic records in each of the four delimited areas. The four areas are (Fig. 5): a) North and Central America, from Alaska to Panama, b) South America, from Colombia to Patagonia; c) the Pacific area, i.e., Australia and the islands of Japan, Taiwan, Indonesia, East Timor, Papua New Guinea, New Zealand, and Hawaii; and d) the Old World, i.e., Europe, Africa (including Macaronesian islands and Madagascar) and Asia (excluding the islands of the Pacific area).

## MORPHOLOGY

### Duration and Habit

The 21 annual species and the three biennial (two of them sometimes annual) are distributed among the sect. *Batrachioidea*, the sect. *Divaricata*, the sect. *Ruberta*, the sect. *Trilopha*,

the sect. *Dissecta*, the sect. *Geranium*, and the sect. *Lanuginosa*. Annuals and biennials are easily distinguished by the absence of a rhizome and by their simple taproot, with thin secondary roots. The remaining species of the genus are perennials.

Perennials are usually herbaceous with a well-developed, prostrate to erect, aerial stem and a vertical to horizontal rootstock. The species from the *Sibbaldioides Group*, the *Sessiliflorum Group* (sect. *Geranium*) and the sect. *Subacaulia* are an exception to this pattern; they are acaulescent, usually cushion-like, with cymules arising directly from the rootstock. This growth form seems an adaptation to the extreme climatic conditions at high elevations also found in other groups of vascular plants.

The species of sect. *Neurophyllodes* are all shrubs. Among them, *G. hanaense*, *G. hillebrandii*, and *G. kauaiense* are dwarf shrubs, decumbent and often rooting at the nodes. *Geranium arboreum* and *G. multiflorum* are well-developed shrubs, the first reaching up to four meters in height. This is quite unusual in *Geranium*, but not unique. Some species from South America: *G. exallum* and *G. jahnii* (sect. *Paramensia*), and *G. loxense* (sect. *Geranium*) are dwarf shrubs in paramo habitats, while *G. lignosum* and *G. lindenianum* (sect. *Geranium*) are more developed shrubs. Three species from South Africa, *G. brycei*, *G. pulchrum*, and *G. robustum* (and probably *G. amatolicum* and *G. grandistipulatum*), are also described as shrubs, although somewhat less than four meters in height. According to Hilliard & Burtt (1985: 176) the latter are not true shrubs although they have woody stems that persist for more than one season. A pachycaul

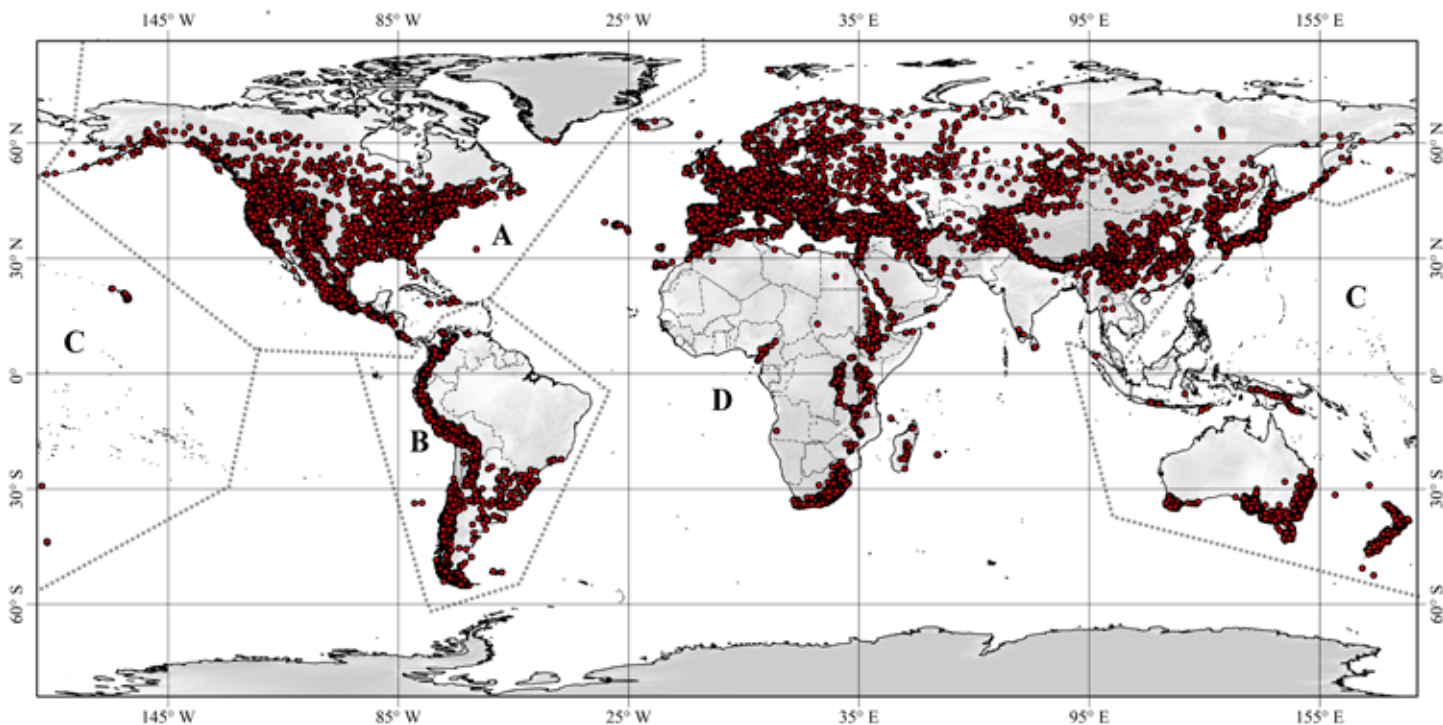

Fig. 5. Map showing the distribution of the genus *Geranium* and the four areas delimited to arrange the regional keys: a) North and Central America, b) South America, c) the Pacific area, and d) the Old World.

habit is found in the Macaronesian perennials *G. palmatum* and *G. reuteri*, and the monocarpic *G. maderense*.

Some species, mainly from sect. *Geranium*, but also from sect. *Aculeolata* and sect. *Neurophyllodes*, are characterized by prostrate to ascending stems occasionally rooting at the nodes. An unusual pattern is seen in *G. stoloniferum*, which has a basal rosette of leaves giving rise to one erect main stem with a well-developed dichasial inflorescence and one or two herbaceous procumbent stolons. These epigeal stolons, borne from the inner part of the rosette, reach up to 20 cm long, have several pairs of leaves, and terminate in a bud. They seem to result from the growth of one year. *Geranium stoloniferum* has also some hypogeous, lignified stolons. These are borne from the external part of the rosette, are ramified, and reach up to 100 cm long. The lignified stolons bear several secondary rosettes and terminate in a rosette as well. It is possible that these structures originate from herbaceous stolons. Epigeal stolons have also been found in five species of the *Papuanum* Group.

Some species from the northern and central Andes (the *Sibbaldioides* Group and the *Multiceps* Group) and from New Guinea (the *Papuanum* Group) have structures that have been termed “vegetative stems” in order to facilitate description. These species produce a kind of bud towards the apex of the branches, sometimes quite long and covered by stipules (usually without petiole remains), which bears a rosette of leaves and an inflorescence (see drawings for a better understanding). This structure may represent the growth of each vegetative period.

The underground parts of perennials (roots and rootstocks) are generally not thoroughly studied owing to their poor representation in herbaria.

Probably as a response to arid climatic conditions from the Mediterranean Basin and central Asian highlands some groups have developed tuberculate rootstocks (sect. *Tuberosa* and two species of the *Pylzowianum* Group). In a similar way, the turnip-shaped rootstocks found on species of the *Sessiliflorum* Group, the *Solanderi* Group, the *Potentillifolium* Group, the *Diffusum* Group, the *Rupicola* Group, the *Mexicanum* Group, the *Renifolium* Group and the sect. *Incana* may have evolved to withstand drought conditions in South Africa, South America, Mexico and Oceania.

Species with rootstocks that have thickened roots are widespread among different groups of *Geranium*. Normally these roots are arranged along the rhizome but in some species of the *Palustre* Group, the *Krameri* Group, the *Sibiricum* Group and one of the *Pylzowianum* Group (sect. *Geranium*) plus in one species of sect. *Dissecta* the thickened roots are grouped in a fascicle.

## Indumentum

Most *Geranium* species are covered in variable density by various types of hair. Exceptionally some species are almost entirely glabrous (e.g., *G. glaberrimum* and *G. lucidum*).

The following types of hairs, all simple and uniseriate (Theobald & al. 1979), have been found in *Geranium* (Figs. 6-8). (1) Eglandular hairs (0.1-5.4 mm long), unicellular, smooth or papillose, appressed, more or less uncinatate or patent; these occur in a variable frequency in most species. In *G. schiedeanum* and *G. lozanoi* some hairs have a circular basal portion and others a narrowly elliptic one. The second type appears under the microscope as “plane” or “scale-like”, particularly if it is very short. According to Payne (1978), all these hairs belong to the “subulate” type. (2) Glandular

(Based on: a, Miyamoto 10140, E; b, Cuadros & Gentry 2782, MO; c, Lebrun 7308, P).

hairs (0.1–3.9 mm long), with a foot consisting of cylindrical or decussate cells and an apical broader cell; rarely the apical cell is of similar width to that of the basal cell (e.g., *G. maculatum*); these occur on almost all structures of plants, sometimes restricted to the inflorescences. (3) Plane, glandular hairs (0.4–1.2 mm long), with two to four cells, usually papillose. These are restricted to the leaves in some species of sect. *Polyantha*, sect. *Ruberta*, and sect. *Trilopha*. (4) Short glandular hairs (< 55  $\mu$ m long), smooth, usually of two cells, but sometimes with a bicellular foot, are present in all species studied here. Because these are visible only at high magnification, they are not included in the descriptions. Additionally, *G. aculeolatum* has sharp retrorsely curved prickles 0.5–1.2 mm long on the stem and inflorescence. In *G. latilobum* the middle portion of the stem bears abundant stout eglandular hairs, some of them prickly-like.

The presence of glandular hairs is a character to be used taxonomically with caution. Some species consistent-

ly lack glandular hairs, but in others the presence of glandular hairs varies even among individuals.

A detailed study of the glandular hairs of *G. robertianum* and its secretions is provided by Pedro & al. (1990, 1991).

## Leaves

*Geranium* leaves are usually palmatifid (Fig. 9), sometimes palmatisect (Fig. 10), polygonal in outline, with five segments, cordate at the base, petiolate and with a couple of stipules. Basal leaves are usually arranged in a persistent or deciduous rosette. In shrubby species the basal leaves are soon deciduous and are not present on mature plants or are unknown. Cauline leaves are similar in shape to the basal leaves, although they become progressively shorter towards the apex of the shoot. A diagram of dimensions used to describe the leaf lamina is shown in Fig. 11. The primary division of the leaf is called a "segment" and the subsequent divisions are called "lobes".

Fig. 9. Photographs showing palmatifid leaf laminas of *Geranium*. a. *G. atlanticum* (sect. *Geranium*). b. *G. renardii* (sect. *Lanuginosa*). c. *G. thessalum* (sect. *Subacaulia*). d. *G. wilfordii* (sect. *Geranium*). (Based on: a, Quintanar 3244, MA; b, Aedo 4478, MA; c, Herrero & al. 3600, MA; d, Farges 110, MA).

*Geranium ornithopodioides* has peltate leaves (with the petiole attached to the blade not by the margin), an unknown trait in other species of the genus.

The Hawaiian endemic species of sect. *Neurophyllodes* have a distinctive leaf lamina. It is unlobed, with an ovate to obtriangular-cuneiform outline, with 3-7 teeth restricted to the apex or almost to the base and with a cuneate base. In the sect. *Paramensia*, *G. jahnii* has quite similar leaves, obtriangular in outline, cuneate and with a tridentate apex, and *G. exallum* differs from all other species in the genus in its entire, narrowly lanceolate, ericoid lamina. In the sect. *Geranium*, four species from the northern Andes (*G. digitatum*, *G. maniculatum*, *G. rhomboidale*, and *G. trujillense*; the *Sibbaldioides* Group) plus *G. cavanillesii* (the *Multiceps* Group), have digitate laminas, with the lateral segments turned upward. *Geranium campii* (the *Sibbaldioides* Group), also from this region, has a very distinctive lamina, which is tripartite with broadly lanceolate segments. *Geranium azorelloides* (the

*Sibbaldioides* Group) has a rather different tridentate lamina that is quite similar to that of *G. jahnii* (Figs. 12, 13).

The cauline leaves of *Geranium* are opposite in most species but alternate leaves are also common. In species of different groups the middle cauline leaf (usually one, sometimes two) is alternate but the more distal leaves are opposite. In contrast, in five species of the *Papuanum* Group the cauline leaves are opposite while those of the buds alternate. *Geranium oaxacanum* shows a trait unknown in any other species of *Geranium*: a whorl of 3-6 leaves at the first branch point of the inflorescence. Sometimes a second whorl of leaves is present between the base and the first branch point.

The six species of sect. *Neurophyllodes* share a singular feature: an abscission zone at the base of the petiole, just at the junction with the stipules. It should be noted that two species from sect. *Paramensia* also have leaves with an abscission zone. In these species, however, the abscission zone is between the lamina and the petiole.

Fig. 10. Photographs showing palmatisect leaf laminas of *Geranium*. a. *G. argenteum* (sect. *Subacaulia*). b. *G. ayavacense* (sect. *Geranium*). c. *G. palmatum* (sect. *Ruberta*). d. *G. retrorsum* (sect. *Geranium*). (Based on: a, Aedo 20891, MA; b, Aedo 16622, MA; c, Aedo 9697, MA; d, Crawford 2474, MA).

Fig. 11. Diagram of characters used to describe leaf lamina. a. Lamina length. b. Lamina width. c. Segment length. d. Main-sinus length. e. Secondary sinus length. f. Maximum width. g. Segment width at the base.

Each leaf has two stipules, one on either side of the petiole base. The stipules are usually free and lanceolate (in some species ovate), sometimes with a setaceous or short bifid apex (Fig. 14). In a part of the species of the *Sibbaldioides* Group they end in 1-3 short bristles. In some species each stipule is connate with one stipule of the opposite leaf for most of its length. This feature has been observed in species of the *Arabicum* Group, the *Krameri* Group, the *Palustre* Group, the *Papuanum* Group, the *Refractum* Group, the *Wallichianum* Group, all of the sect. *Geranium* and in *G. aculeolatum* (sect. *Aculeolata*) (Fig. 15). In a part of these species this character is variable because the stipules are free in some nodes and connate in others of the same individual. In the six species of sect. *Neurophyllodes* the stipules of each leaf (leaves are alternate) are fused at the base to form a sheath that surrounds the next portion of the branchlet. When the petioles and leaf lamina abscise from the stem, the branchlets ac-

Fig. 12. (Based on: a, Cuatrecasas & Willard 26343, MA; b, Remy 828, MA; c, Riina & al. 597, MA; d, Sklenář 15822, MA).

quire a unique aspect because of the persistent, sheathing stipules (Fig. 16). The stipules of the South African species of sect. *Incana* are lanceolate to flabelliform in outline, with 2-9 narrow and deep lobes (Fig. 16).

### Inflorescence

Acaulescent species (e.g., sect. *Subacaulia*, *Sessiliflorum Group* or *Sibbaldioides Group*), have a reduced inflorescence of cymules arising directly from the rootstock. In the caulescent species the usually 2-flowered cymules are in a dichasially arranged inflorescence, sometimes with monochasial branches (e.g., sect. *Tuberosa*, *Caespitosum Group*, *Multiceps Group*, *Sylvaticum Group*). It is more frequent, however, that 1- or 2-flowered cymules are borne at the nodes along the stem, i.e., in a monochasial cyme. In both cases some species may have umbel-like aggregates of cymules at the top of each branch in which the peduncles are usually short or absent.

The shrubby species of sect. *Neurophyllodes* (from Hawaii) have a complex inflorescence. Along each branch some floriferous branchlets can occur. These partial inflorescences have 1-flowered cymules grouped into

(1)7-12(60)-flowered cymes at the end of a brachyblast. Some axillary leaves occur on the basal part of these inflorescences. From each node usually one single-flowered cymule is borne. All nodes of the inflorescences, i.e., the base of the peduncle and the partial branchlets have abscission lines. The abscission of peduncles together with the fruits may contribute to seed dispersal as a complementary mechanism of autochory, superposed upon the ballistic seed-ejection system of this group of *Geranium*.

Some robust species from Macaronesian islands also exhibit a complex inflorescence. *Geranium palmatum* and *G. reuteri* (sect. *Ruberta*) produce a terminal inflorescence with axillary branches arising below the uppermost rosette leaves, which is basically dichasial with 2-flowered cymules. However, the suppression of internodes, the absence of growth in certain axes, and the abortion of flowering peduncles combine to display a complex inflorescence with numerous flowers together. *Geranium maderense* (sect. *Ruberta*) has a similar but immense inflorescence with four to eight crowded terminal branches at the apex of the rosette leaves.

In some shrubby species from South Africa (sect. *Incana*) the inflorescence shows peduncles opposite to the

upper leaves along the branches forming large compound and complex cymes, lacking leaves on the upper nodes and with ultimate peduncles mostly 2-flowered.

In species with 2-flowered cymes there are four whorled bracteoles dividing the peduncle from the pedicel, while in those with 1-flowered cymes there are two opposite bracteoles (except when they lack pedicels) (Fig. 17). In the species of sect. *Neurophyllodes* the two bracteoles on each peduncle are not sheathing, but instead their bases overlap on one side of the peduncle, exposing the opposite part and giving a sheathed appearance (Fig. 17). Some species of the *Papuanum Group* from New Guinea also have quite similar bracteoles.

### Calyx

The sepals form a quincuncial calyx. The two inner sepals are usually less pubescent than the others. The external surface of each sepal is smooth, sometimes with thickened nerves. In *G. glaberrimum* and *G. lasiopus* (sect. *Ruberta*) the

three outer sepals have 2-3 longitudinal ribs and the inner are smooth, while in *G. lucidum* (sect. *Ruberta*) the three outer sepals have lengthwise keels and transverse flaps between these, and the two inner are  $\pm$  smooth.

The sepals may be somewhat elongated on the fruit but they are obviously only accrescent in a few scattered species of sect. *Geranium*, sect. *Lanuginosa* and sect. *Trilopha*, most of them annuals. The sepals of most species end in a distinct mucro. Only *G. planum* (sect. *Geranium*) and *G. makmelikum* (sect. *Subacaulia*) lack mucro in all or part of specimens examined. In descriptions and key, the length of the sepal does not include the length of the mucro.

Kenda (1956) studied the presence of subepidermal calcium oxalate crystals in the sepals of some geraniums.

### Corolla

The actinomorphic corolla of *Geranium* has five petals that are usually erect-patent or, more rarely, patent. Two spe-

Fig. 17. Photographs showing whorled, opposite or overlapping bracteoles of *Geranium*. a. *G. nodosum* (sect. *Geranium*). b. *G. sanguineum* (sect. *Geranium*). c. *G. cuneatum* subsp. *cuneatum* (sect. *Neurophyllodes*). (Based on: a, Calvo & al. 6606, MA; b, Galán Cela 1261, MA; c, Remy 828, MA).

cies of sect. *Erodioidea*, five species of the *Refractum* Group (sect. *Geranium*) and one the *Caespitosum* Group (sect. *Geranium*), however, have reflexed petals. The corolla of *G. arboreum* is unique in the genus, with the petals arcuate, the upper three erect (with revolute apex), the lower ones reflexed, forming a zygomorphic corolla. The two species of sect. *Unguiculata* have also a zygomorphic corolla, while in *G. palmatum* (sect. *Ruberta*) it is slightly zygomorphic.

The petal apex is usually rounded, but in some species it may be also retuse or slightly notched, or even emarginate. The base gradually narrows or more rarely differs into a claw in some species of subg. *Geranium* and subg. *Robertium*. In the ten species of sect. *Ruberta* and in *G. rotundifolium* the claw is bicrenate on the adaxial side. Petal length varies greatly and is taxonomically useful. Annual species have short petals, but some perennial species, such as *G. sibiricum* or *G. core-core*, also show this trait. In *Geranium* few species have absolutely glabrous petals. It is more common that they have some short hairs on the base, especially at the basal margins. In some groups of sect. *Geranium* (i.e.: the *Caespitosum* Group, the *Hernandesii* Group, the *Krameri* Group and others single species) and in *G. glanduligerum* (sect. *Erodioidea*), the petals are hairy on the basal 1/5 to 3/4 of the adaxial surface. The color of the petals varies from white, pale pink or blue to a more or less intense purple, or exceptionally blackish. In *G. arboreum* the petals are reddish. In some species of sect. *Geranium*, sect. *Trilophia*, and sect. *Subacaulia* the petals have a distinctive dark basal spot.

## Androecium

The flower has two whorls of five fertile stamens each. The stamens are usually shorter than the petals, except in species with patent to reflexed petals. The anthers are dorsifixed and dehisce by longitudinal slits. The antepetalous anthers (inner whorl) dehisce first, followed by the antepetalous whorl. Endress (2010) studied deeply the anatomic and organizational aspects of obdiplostemony of the androecium of *G. robertianum*. *Geranium pusillum* (sect. *Batrachioidea*) and *G. texanum* (sect. *Geranium*) are two annual species with the external whorl lacking anthers and with reduced filaments.

The filaments are usually lanceolate, but in some species they have a broad triangular base and an abruptly narrowed apex; they are usually glabrous or with short hairs, but some species (e.g., *G. reinii*) have hairs up to 4.2 mm long. The color of the filaments varies from white or pink to more or less deep purple. The exception are some species of sect. *Trilophia* and sect. *Geranium*, which have black filaments at least at the tip.

*Geranium* usually has five hemispheric nectaries alternate with the petals. In *G. lucidum* the nectaries are strongly reduced. *Geranium sinense* is the only species in the genus with a nectary forming a ring all around the flower. Nectaries can be glabrous, with a tuft of hairs at the apex, or dorsally hairy. Mirimanoff (1941), Link (1990) and Konarska & Masie-

rowska (2019) provided further data about the nectar composition, affinities and structure of the *Geranium* nectaries.

## Pollen

The pollen of *Geranium* is tricolporate and more or less isodiametric. In size they range from 47 to 123  $\mu\text{m}$  (polar diameter) and 42 to 120  $\mu\text{m}$  (equatorial diameter) (Stafford & Blackmore 1991; Verhoeven & Venter 1992). The exine bears reticulate ornamentation formed by baculate, clavate, or gemmate supracteal elements, which is defined as *Geranium*-type (Bortenschlager 1967; Stafford & Blackmore 1991). There is some variation in the size of supracteal elements, having gemmate elements that may protrude further from the reticulum giving the grain an irregular outline. On this basis some subtypes of little taxonomic interest were defined. The exine ornamentation studied in the four sections of subg. *Erodioidea* (54 % of the species studied), the five sections of subg. *Geranium* (62 % of the species studied) and all species of subg. *Tuberosa*, always shows the *Geranium*-type (Bortenschlager 1967; Gagnepain 1903; Lu & al. 1996; Park & Kim 1997; Perveen & Gaiser 1999; Shehata 2008; Stafford & Blackmore 1991; Tan & al. 1996; Velasco 1992b; Verhoeven & Marais 1990; Verhoeven & Venter 1992) (Figs. 18-20).

In contrast, in the species of sect. *Trilophia* and sect. *Polyantha*, both of subgenus *Robertium*, the exine shows a striate-rugulose pattern, similar to that found in *Erodium*, which is defined as *Erodium*-type (Aedo 2016; Aedo & al. 2016; Bortenschlager 1967) (Fig. 21). However, Shehata (2008) indicated that *G. trilophum* has *Geranium*-type pollen, and Park & Kim (1997) and Perveen & Gaiser (1999) show the same for *G. ocellatum*. This could be the result of a mistake in the identification of these specimens. Thus, the identity of the vouchers should be revised to confirm such type of ornamentation in sect. *Trilophia*. In the remaining species of subgenus *Robertium* (sect. *Batrachioidea*, sect. *Divaricata*, sect. *Ruberta* and sect. *Unguiculata*), the pollen is of the *Geranium*-type (Bortenschlager 1967; Gagnepain 1903; Park & Kim 1997; Perveen & Gaiser 1999; Stafford & Blackmore 1991; Tan & al. 1996; Velasco 1992b; Verhoeven & Marais 1990; Weber 1996).

The identity of the fossil pollen grains attributed to *Geranium* and *Erodium* (Van Campo 1989: 16 fig. 18-19, 19 fig. 1-10) should be confirmed before to use them as evidence to support phylogenetic reconstructions.

## Gynoecium

The gynoecium comprises five carpels, each with two ovules, of which only one develops into a mature seed. According to Albers & Van der Walt (2007) the "ovules are anatropous, bitegmic and crassinucellate. Embryo sac development is of the *Polygonum* type; the early endosperm conforms to the Nuclear type, and both endosperm and nucellus are later resorbed by the embryo". The ovary has five locules and is lobed. The five styles are fused into a col-

umn, divided at the apex into five branches, each of which has a stigmatic surface on the adaxial side. Erbar (1998) studied the ontogeny of the coenocarpous gynoecium of *Geranium* in the case of *G. sanguineum*. Dragunova (1985) studied the ultrastructure of the integuments and nucellus in *G. gracile*. Kumar (1977) described the embryology of *G.*

*lucidum*, *G. nepalense* and *G. wallichianum* and Phouphas (1950) that of *G. robertianum*.

### Fruit

The fruit of *Geranium* is a schizocarp. Figure 22 shows the characters used to describe the fruit. After fertilization a prominent rostrum develops proximal to the style. The rostrum in some species has a narrowed apex of stylar origin and always bears the remnants of the five stigmas. At maturity the carpel shows two main parts: (1) a locus containing the seed, called the mericarp, and (2) a sterile portion forming a ribbon-like band (the awn), which is derived from the rostrum that has a central axis or columella.

The type of fruit discharge is the basis for the subgeneric classification proposed by Yeo (1984). Yeo (1984) described three main classes of discharge mechanism, one of which has three subclasses.

In the “*Erodium*-type” of discharge, the entire mericarp, including the coiled awn, is propelled over a short distance. The seed remains inside of mericarp, because the lateral margins of the mericarp are close together on the adaxial side and prevent the seed from falling off. The “*Erodium*-type” of discharge is found in the four sections of subg. *Erodioidea*. In this type of fruit the base of the mericarp usually narrows into a beak and ends in a thickening or callus. It seems that the function of this callus would be to facilitate the burial of the mericarp, rather than to prevent the seed from falling. The mericarps surface has usually some transverse ribs towards the apex. Three species of sect. *Subacaulia* have lost the basal callus. In contrast with other species of the subgenus *Erodioidea*, the mericarps of *G. aculeolatum* end abruptly, lacking the basal beak (Figs. 23, 24).

In the “carpel-projection type” of discharge the whole mericarp, containing the seed and without the awn, is dispersed by the propelling force of the explosive recurvature of the awn (Figs. 25-27). The “carpel-projection type” of discharge is found in the six sections of subg. *Robertium*. In the sect. *Divaricata* the mechanism of propelling the mericarp is not operative because the rostrum is not well developed and thus the mericarp including the seed is ejected only a short distance. Nevertheless Yeo (1984) classified this

section under the subg. *Robertium* because "... they have a sculptured mericarp that is freed with the seed inside it and without the awn". In sect. *Divaricata* the seed remains inside of the mericarp, because the lateral margins of the mericarp are close together on the adaxial side and prevent the seed from falling. Three of the four species of sect. *Batrachioidea* have smooth mericarps but otherwise they fit well with the "carpel-projection type". Two species of sect. *Ruberta* have a strand of fibers derived from the beak, attached near the apex on either side. They have an adhesive property so that the mericarps are suspended in other plants when they are ejected. According to Yeo (1973a: 305) "The fibers are formed in two bundles, one along either side of the elater, but on their release they form a single strand except near their points of attachment, which are just below the apex of the carpel." Three of the six species of sect. *Trilophia* have a peculiar mericarp with two longitudinal toothed wings bent dorsally to form a trough-like structure. The five ribbon-like bands of the rostrum are

usually parallel in *Geranium*, but in all species of sect. *Trilophia* they are twisted. A similar twist is found in the species of subg. *Tuberosa*.

In the "seed-ejection type" of discharge each single seed is launched by the explosive recurvature of the awn, and the mericarp remains attached to the awn, which usually remains apically attached to the columella. There are three variants of the mechanism retaining the seed within the mericarp during the pre-explosive interval. This permits a division into three subclasses.

In the first subclass there is no structure for retaining the seed in the pre-explosive interval. Instead, the mericarp is twisted at its attachment to the awn and, consequently, the orifice faces almost horizontally. The upper part of the mericarp is longitudinally compressed, probably strengthening the connection between the awn and the mericarp and favoring the twisting of the mericarp. The five ribbon-like bands of the rostrum are twisted. This type is found in the two sections of subg. *Tuberosa* (Figs. 28, 29).

SEM photographs showing mericarps of the “seed-ejection type” of discharge in species of *Geranium* subg. *Tuberosa*. a. *G. bohemicum* (sect. *Lanuginosa*). b. *G. ibericum* (sect. *Lanuginosa*). c. *G. kotschy* subsp. *charlesii* (sect. *Tuberosa*). d. *G. malviflorum* (sect. *Tuberosa*). (Based on: a, López s.n., MA-213282; b, unknown collector, BR-825853; c, Lipsky 3432, LE; d, Davis 59451, BM).

In the second subclass the seed is retained in the mericarp during the pre-explosive interval by a part of the mericarp wall, which projects as a prong. This prong has the same texture as the rest of the mericarp wall. This type is found in the sect. *Dissecta* (subg. *Geranium*) (Figs. 28, 30). Yeo (2002a: 39) has suggested that subclasses first and second might deserve the rank of subgenus. In the present work this range has only been accepted for the first group due to the strong morphological differentiation of its fruits.

In the third subclass the mericarp has a basal callus with a cluster of bristles at the lower end, which prevents the seed from falling out prematurely during the pre-explosive

interval. This type is found in the remaining groups classified into the subg. *Geranium* (Figs. 30-32).

In the three subclasses of the “seed-ejection type” the mericarp is smooth, occasionally with 1-3 transverse veins at the apex.

The rostrum of some species of *Geranium* is gradually narrowed toward the apex, whereas in others it terminates abruptly in a narrow apex, in which case the apical portion of the rostrum is easily differentiated from the basal one. This narrowed apex is of taxonomic utility at the species level.

Structural aspects of the hygroscopic movements of the awn in Geraniaceae are analyzed by Abraham & Elbaum (2013).

## Seeds

The seeds are more or less ellipsoid and slightly compressed. Most species of the genus show a finely reticulate surface. The depth and length of the alveolus vary within some species, suggesting that this feature has little taxonomic value. In many species of subg. *Robertium* (but also in few cases of those of the subg. *Geranium* and subg. *Tuberosa*) the surface appears smooth at low magnification, but a reticulum is revealed at high magnification (Fig. 33). Exceptionally, the seeds of *G. rotundifolium* and few other species show a distinct reticulation even to the unaided eye (Fig. 34). The outer layer of the seed-coat has cells with anticlinally thickened walls, forming a polygonal pattern. These anticlinally thickened walls, usually straight in the genus, are more or less curved in the seeds of the sect. *Neurophyllodes*, giving the seed-coat surface a distinctive reticulate-sinuous aspect. Seeds are glabrous in *Geranium*, except in *G. rupicola*, which has scattered hairs on the seed surface (Fig. 35).

According to Albers & Van der Walt (2007) the seeds are campylotropous with large embryos and strongly folded cotyledons, when viewed in transverse section, and have no or very little endosperm; they are rich in lipid substances and poor in starch (see also Boesewinkel & Been 1979; Boesewinkel 1988, 1997; Yeo 1990). Cotyledons usually have an entire margin but in some species they have one or two notches on each side. This feature has been found only in *G. aculeolatum* (with two notches on each side) (subg. *Erodioidea*), *G. albanum* (subg. *Robertium*), *G. aristatum* (subg. *Erodioidea*), *G. bohemicum* (subg. *Tuberosa*), and *G. divaricatum* (subg. *Robertium*).

Specific studies about *Geranium* seeds production, development, dormancy, germination and seed survival are addressed in the following papers: Abrams & Dickmann (1984), Ågren & Willson (1992), Baskin & Baskin (1974), Gama-Arachchige & al. (2010, 2011, 2012), Herrera (1991), Meisert (2002), Meisert & al. (1999), Milberg (1994), Raunkiaer (1888), Roberts & Boddrell (1985), Van Assche & Vandeloos (2006), Vandeloos & Van Assche (2010) and Varga & al. (2015).

## CHROMOSOME NUMBERS

Preliminary studies with chromosome numbers on scattered species of *Geranium* were published by Heitz (1926) and Tjebbes (1928). The first detailed study of the family is provided by Gauger (1937). Soon after, the relevant contribution by Warburg (1938a, 1938b) appeared entitled "Taxonomy and Relationship in the Geraniales in the Light of their Cytology". As was customary, the information on the localities of origin of the individuals counted in these early works was fragmentary and there are no herbarium vouchers explicitly indicated. The lack of herbarium vouchers is currently an obstacle in clarifying some dubious chromosome numbers. Although there have been many subsequent contributions, the works of Van Loon (1984a, 1984b, 1984c) are for their exhaustiveness a reference for cytological studies of *Geranium*. Unfortunately these studies only refer to European species. Many species from Africa, America, Asia and Oceania as yet remain uncounted (see Appendix 1).

All the cytologically known species of subg. *Erodioidea* (ten of sect. *Subacaulia* and three of sect. *Erodioidea*) are diploid ( $2n = 28$ ; except *G. ponticum* whose count of  $2n = 26$  should be confirmed). No information is available from sect. *Aculeolata* and sect. *Brasiliensia*. Only *G. subcaulescens* and *G. reflexum* have both diploid and tetraploid numbers. A different number has been proposed (Quézel 1957: 393) for *G. nanum* ( $n = 13$ ), but it is not correct according to Guittonneau (1975: 200). Lastly, Tschermark-Woess & al. (1954: 97) and Nagl (1962: 448), studying somatic polyploidization and endomitosis, proposed  $2n = 14$  for *G. phaeum*, but according to Yeo (1984: 25) this number should be confirmed.

Regarding the subg. *Geranium* no cytological information is available from sect. *Paramensia*. In sect. *Incana* only one of the 22 species has been counted: *G. caffrum* ( $2n =$

22). In sect. *Neurophyllodes* only one of the six species has been counted: *G. arboreum* ( $2n = \text{ca. } 50$ ). In sect. *Dissecta* it has been well documented that *G. dissectum* has  $2n = 22$ , and both *G. crenophilum* and *G. sintenisii*,  $2n = 26$  chromosomes. *Geranium asphodeloides* has been reported to have  $2n = 24, 26, 28$  and  $30$ . Strid & Franzén (1981: 835) found some chromosomal fragments in addition to the 30 A chromosomes. The sampling in sect. *Geranium* is quite complete in Europe and to a lesser extent in Asia, where 40 species were counted almost all with  $2n = 28$ . In Africa only *G. arabicum* has been counted with  $2n = 28$  as well. Older chromosome counts  $2n = 24$  of *G. pratense* should be confirmed. Belaeva & Siplivinsky (1975: 869) found plants in this species with supernumerary chromosomes in addition to regular diploids  $2n = 28$ . Chromosome numbers of *G. sanguineum* different to  $2n = 84$  should also be confirmed. Van Loon (1984b: 271), only found  $2n = 84$  in this species, and suggested that it is a hexaploid with basic number  $x = 14$ . Sansome (1936: 362) indicated that there is autohexaploid segregation of flower color in *G. sanguineum*. This section has not been extensively studied in America and Oceania (16 and 9 species, respectively). In both regions the counts ranges from 26-28 to 112. The most common numbers are  $2n = 52$  and  $2n = 56$ .

Eleven of the 17 species of the subg. *Tuberosa* are cytologically known. Regarding sect. *Tuberosa* only four taxa have been counted: *G. libanoticum* ( $2n = 28$ ), *G. macrostylum* ( $2n = 28, 42$ ), *G. malviflorum* ( $2n = \text{ca. } 56$ ) and *G. tuberosum* ( $2n = 28$ ). Van Loon (1984b: 269) indicated that the plants of *G. macrostylum* with  $2n = 42$  have a high percentage of abnormal pollen grains and do not produce seeds. He suggested that they may be autotriploids. The two annual species of sect. *Lanugiosa* are *G. bohemicum* ( $2n = 28$ ) and *G. lanuginosum* ( $2n = 48$ ). According to Van Loon the ba-

sis chromosome number of *G. lanuginosum* is probably  $x = 14$ , and its number  $2n = 48$  may have originated from a dysploid. Only five more species of this section have been counted: *G. gracile* with  $2n = 26$ , *G. gymnocaulon*, *G. ibericum*, *G. libani* and *G. platypetalum* with  $2n = 28$  in all cases, but with some additional numbers to be confirmed in *G. ibericum* ( $2n = 56$ ), and *G. platypetalum* ( $2n = 42$ ).

There is uneven information regarding the six sections of the subg. *Robertium*. The four species of sect. *Batrachioidea* have  $2n = 26$ . It seems that some different numbers attributed to these species should be disregarded (Van Loon 1984b, 1984c). In the sect. *Divaricata*, *G. divaricatum* has  $2n = 28$  while *G. albanum* has  $2n = 20$ ; in both species there are old counts which are difficult to verify (Van Loon 1984b, 1984c). The sect. *Trilopha* and sect. *Polyantha* are poorly studied. In the former only two species were counted, *G. brevipes* with  $2n = 56$  and *G. favosum* with  $2n = 50$ . In the latter only *G. polyanthes* was studied resulting in  $2n = 28$ . In sect. *Unguiculata*,  $2n = 46$  was found in *G. dalmaticum*, while *G. macrorrhizum* showed a variable number of chromosomes, in some cases  $2n = 46$  and in others from  $2n = 87$  to  $93$  (see Van Loon 1984b: 269 for further details). All species of sect. *Ruberta* were studied. The figures obtained in this group are quite heterogeneous. According to Van Loon (1984c: 283) *G. lucidum* has a polyploid series ( $2n = 20$  to  $44$ ) with the basic chromosome number  $x = 10$ . The tetraploid cytotype ( $2n = 40$ ) is the most common and it comprises an ascending dysploid series. According to Yeo (1973a: 314) and Wilder-Kiefer & Yeo (1987), *G. purpureum* ( $2n = 32$ ), *G. robertianum* ( $2n = 64$ ) and *G. yeoi* ( $2n = 128$ ) probably represent a polyploid series. This author indicates that the triploid hybrid *G. purpureum*  $\times$  *G. robertianum* formed  $n$  univalents and  $n$  bivalents at the first division of meiosis, strongly suggesting that *G. robertianum* is an allopolyploid with *G. purpureum* and an unknown species as parents. Yeo & Wilder-Kiefer (1990: 2) pointed out that the results of their study on the presence/absence of amino acids are congruent with the hypothesis of the allopolyploid origin of *G. robertianum* and the autopolyploid origin of *G. yeoi* [as *G. rubescens*]. The remaining species of the section are: *G. glaberrimum* ( $2n = 30$ ), *G. cataractarum* ( $2n = 36$ ), *G. lasiopus* ( $2n = 48$ ), *G. maderense* ( $2n = 68$ ), *G. palmatum* ( $2n = 68$ ) and *G. reuteri* ( $2n = 128$ ). Wilder-Kiefer & Yeo (1987: 287) reported that the hybrid of *Geranium maderense*  $\times$  *G. cataractarum* formed ca. 16 univalents and ca. 18 bivalents at the first division of meiosis, which strongly suggests an allopolyploid origin for *G. maderense*, with *G. cataractarum* and an unknown species as parents.

According to Van Loon (1984b, 1984c) most species of *Geranium* are diploid with  $2n = 28$  and the main basic chromosome number is  $x = 14$  (Van Loon 1984b, 1984c; Warburg 1938a, 1938b), but other numbers ( $x = 9$  to  $x = 23$ ), mainly in annual species, have also been reported (Van Loon 1984b, 1984c). These data are probably due to a sampling focused on Eurasian species and could change when more species

from Africa, America and Oceania can be studied. Polyploidy appears to be an important pathway for evolution in some groups, like sect. *Ruberta* (Yeo 1973a: 308). It may be interesting to note that in some species from different subgenera (e.g.: *G. asphodeloides*, *G. caeruleatum*, *G. lucidum*, *G. macrorrhizum*, *G. macrostylum*, *G. potentilloides*, *G. reflexum*, *G. subcaulescens*) a variable number of chromosomes have been found. These cytotypes do not differ from each other morphologically.

## BREEDING SYSTEM

It is widely accepted that the species of the genus *Geranium* are predominantly protandrous with an internal whorl of stamens that matures earlier than the external one, and a stigma which matures after pollen dispersal, which favours decreasing selfing processes (Aedo 1996; Knuth 1908; Sprengel 1793; Wilder-Kiefer & Yeo 1987). Several authors, however, have found different variations on this pattern. Philipp (1985) found that plants of *G. brevicale* [as *G. sessiliflorum*] were protandrous at one locality, homogamous at another, and protogynous at a third locality. Martin (1965: 127) reported that *G. maculatum* is predominantly protandrous but also may be partially homogamous. Tofts (2004a: 549) summarized the available information about *G. robertianum*, that may be homogamous, slightly protandrous or protogynous. Protogyny is also reported by Bertin (2001) for *G. robertianum*, and by Knuth (1908) for *G. dissectum* and *G. pusillum*.

Although protandry (or protogyny) suggests a strong preference for outcrossing, in plants with a large number of simultaneously blooming flowers, pollination can occur between different flowers of the same individual. Such is the case reported by Hessing (1986: 467) in protandrous plants of *G. caespitosum*, where "geitonogamous pollination is an extremely common event, probably overwhelming the effects of dichogamy". Moreover, Hessing (1988: 1328) suggested that the low decrease of fertility after selfing of *G. caespitosum* is not caused by self-incompatibility. Asikainen & Mutikainen (2005b: 488) also pointed out that hermaphrodite flowers of *G. sylvaticum* are self-compatible. Wilder-Kiefer & Yeo (1987: 288) indicated that flowers in *Geranium* are fully self-compatible.

Cruden (1976, 1977) emphasized that the Log pollen-ovule ratios are correlated with the breeding system. A substantial decrease in Log P/O suggests a pass from outcross pollination to self-pollination. Aedo & al. (2002) pointed out that some perennial species from the Andes (such as *G. multipartitum* and *G. sibbaldioides*) show low Log P/O ratios, suggesting facultative self-pollination. This is congruent with homogamy observed in herbarium specimens of these perennial species.

Shirk & Hamrick (2014) found that *G. carolinianum*, an annual species with short petals, is incompletely protogy-

nous and that there is a short “period when female stage flowers are available for exclusively outcross pollination, followed by reproductive assurance via delayed self-pollination”. This is interesting because other annuals species with small flowers had been considered strictly homogamous and self-pollinated (Proctor & al. 1996: 332).

In some species of sect. *Trilophia* and sect. *Polyantha* cleistogamous flowers have been found. According to Schönbeck-Temesy (1970) *G. mascatense* and *G. trilophum* frequently produce non-opening, self-pollinating flowers. Kers (1971) reported such cleistogamous flowers for *G. brevipes*, Yeo (2002a: 161, 165) for *G. polyanthes* and *G. ocellatum* and Aedo & al. (2016: 363) for *G. biuncinatum*.

Some species of *Geranium* are gynodioicous, containing female and hermaphrodite plants that coexist. In these species the flowers of female plants usually are significantly smaller than those of hermaphrodites. The anthers produce either no pollen or small, inviable grains. Within the sect. *Geranium* the following gynodioicous species have been reported: *G. caespitosum* (Hessing 1988: 1332, 1989: 235), *G. maculatum* (Ågren & Wilson 1991; Chang 2006; Van Etten & al. 2008), *G. richardsonii* (Williams & al. 2000), *G. sylvaticum* (Asikainen & Mutikainen 2003, 2005a, 2005b; Putrament 1962; Vaarama & Jääskeläinen 1967), and within the subg. *Tuberosa*, *G. kotschyi*, *G. linearilobum*, and *G. tuberosum* (Davis 1970: 98) and *G. peloponnesiacum* (Aedo & al. 2007: 120).

Vaarama & Jääskeläinen (1967: 12) indicated that *G. sylvaticum* may have hermaphrodite flowers, protandrous or rarely homogamous, intermediate flowers with different stages of stamen degeneration, pistillate flowers with rudimentary stamens and pistillate flowers with no stamen mixed in the same individual or located separately in different individuals (gynomonoecy or gynodioecy). These authors reported that gynodioecy and gynomonoecy also has been observed in *G. columbinum*, *G. palustre*, *G. phaeum*, *G. pratense*, *G. pyrenaicum*, *G. robertianum* and *G. sanguineum* (Vaarama & Jääskeläinen 1967: 8).

It was established through the work of Christian Konrad Sprengel, towards the end of the eighteen century, that the pollination of *Geranium* is conducted mainly by insects. Most geraniums are pollinated through this vector (Dlussky & al. 2000; Kandori, 2002; Knuth 1908; Proctor & al. 1996: 17, 48, 66, 67, 99, 103, 145). One exception is the Hawaiian *G. arbo-reum*, that is unique in the genus because of its zygomorphic reddish corolla, which is probably an adaptation to bird pollination. Carlquist (1980: 135) reported that he has seen its flowers visited by a honeycreeper bird (*Himatione* sp.).

Like the case of studies of the chromosome number, studies related to the breeding system are concentrated in very few species, almost all from Europe or North America. The extension of the sampling to species from other areas, with different habitats and pollinators, belonging to different subgroups of the genus, is necessary to provide a more balanced and accurate view of the genus.

## PHYTOCHEMISTRY

Leifertová & al. (1965) studied the tannins of ten species from the former Czechoslovakia and located some differences in those found in *G. phaeum* and *G. nodosum*.

Bate-Smith (1973) studied flavonoids of 60 species of *Geranium* and found that “the genus is very uniform as regards these constituents, differences between species being mainly in regard to the presence or absence of myricetin, leucodelphinidin and leucocyanidin. Gallic acid, hexahydroxydiphenic acid (present as ellagic acid in acid hydrolysates and recorded as such), *p*-coumaric and caffeic acids, quercetin and kaempferol are present in almost every species but not in the same absolute or relative amounts”, and “reduced flavonoids such as flavones and flavanones, O-methylated flavonols and coumarins, which are often helpful in identifying groups of related species, appeared to be completely absent.”

Okuda & al. (1980) studied the distribution of geraniin and mallotusinic acid in Geraniaceae, Euphorbiaceae and other related families. They found that geraniin is the main tannin in the species of *Geranium* from Japan (13 species) and in *Erythroxylum coca* Lam., and that geraniin and mallotusinic acid compose the main tannins in some Euphorbiaceae.

Bate-Smith (1981) studied the leaf tannins of 70 species of *Geranium*, analysing for proanthocyanidins, total galloyl esters, hexahydroxydiphenoylglucose and astringency. He found that “proanthocyanidins are present in most species (prodelphinidin in four) but only rarely in considerable quantities and then not readily extracted. A reaction with potassium iodate characteristic of geraniin (a derivative of dihexahydroxydiphenoylglucose) is given by most species” and that “the considerable differences in astringency between species cannot at present be accounted for in terms of chemical differences.”

Yeo & Wilder-Kiefer (1990) studied essential oils, electrophoretic bands of seed proteins and nectar amino acids of nine species of sect. *Ruberta* and sect. *Unguiculata*. They found that “*G. macrorrhizum* had very much more oil than any other species; the remaining species appeared to be similar to each other and qualitatively different from *G. macrorrhizum* but had a very poor yield of oil” and that the pattern of protein bands and the presence/absence of amino acids are congruent with the hypothesis of the allopolyploid origin of *G. robertianum* and the autopolyploid origin of *G. yeoi* [as *G. rubescens*].

Ivancheva & Petrova (2000) studied flavonoids of eleven species of *Geranium* from Bulgaria and found that “quercetin and its derivatives were the most common aglycones with lesser amounts of kaempferol, myricetin and luteolin.”

A chemical characterization of *G. molle* is provided by Graça & al. (2016) and more specific studies of tannins of *G. thunbergii* is provided by Ishimaru & Shimomura (1991) and for *G. macrorrhizum* by Genova & Ivancheva (1995).

The compilation of the preceding paragraphs is necessarily incomplete because only the taxonomic literature could be examined, but it seems useful to provide a general overview about this topic. As Stuessy & al. (2014) pointed out phytochemical data have been used successfully in systematics but in recent times they have flagged considerably. Regarding *Geranium*, it seems that most the studies have been focused on flavonoids. Their results are obviously interesting to understand the species that have been studied, but at the moment they seem of little taxonomic utility, either to characterize the infrageneric groups or the species.

## DISTRIBUTION AND HABITATS

The genus *Geranium* is distributed throughout most of the world except in lowland tropical areas (Fig. 5). In the New World most of the 123 native species belong to sect. *Geranium*. The exceptions are the two species of sect. *Paramensia* (subg. *Geranium*) growing on the northern Andes and the three of sect. *Brasiliensia* (subg. *Erodioidea*) found in southern Brazil and northern Argentina. Only two species of sect. *Geranium* are native in the New World as well as elsewhere: *G. erianthum* also occurs in eastern Asia, and *G. sylvaticum* is widespread in Europe and western Asia. The Andes in Colombia and Ecuador harbor many endemic species but the greatest diversity is found in Peru (34 species) and in Mexico (36 species).

The Pacific area that includes the islands of Japan, Taiwan, Indonesia, East Timor, Papua New Guinea, Australia, New Zealand, and Hawaii harbor 42 native species, all from sect. *Geranium* except the Hawaiian species of the sect. *Neurophyllodes* (subg. *Geranium*). The greatest diversity is found in New Guinea and Japan, both with 11 species; the species of New Guinea are all endemic, while the diversity of *Geranium* in Japan includes three endemic species and eight species shared with mainland Asia, one extending to North America. Other areas of high diversity of *Geranium* in the Pacific area are Australia and New Zealand (nine species, all endemic), and the Hawaiian Islands (six species, all endemic).

In Sub-Saharan Africa the genus is generally poorly represented. The richest area is South Africa where most of the 22 species of sect. *Incana* are endemic, some of them reaching the mountains of southeastern Africa. The only representative of sect. *Aculeolata* (subg. *Erodioidea*) is spread across the highlands of eastern Africa from Ethiopia to Malawi. Most of the seven species of the sect. *Trilopha* (subg. *Robertium*) are found in the Horn of Africa area and the nearby Arabian peninsula, but one reaches the eastern and western mountains of tropical Africa and another is endemic to the Himalayas. The sect. *Ruberta* (subg. *Robertium*) is represented in eastern mountains of tropical Africa by one non-endemic species, and the sect. *Geranium* by three species, one endemic from Madagascar.

The richest area both in number of species and in diversity of sections and subgenera is the region that includes the mountains around the Mediterranean Basin, the Caucasus, central Asia, the Himalayas and China. In this area the six sections of the subg. *Robertium* are found, the two sections of the subg. *Tuberosa*, two of the four sections of the subg. *Erodioidea* and two of the five sections of the subg. *Geranium*.

The 15 species of sect. *Subacaulia* (subg. *Erodioidea*) and the three species of the sect. *Erodioidea* are found in the mountains around the Mediterranean Basin, although a species of the latter group reaches northern Europe.

The sect. *Tuberosa* (seven species), found from the western Mediterranean to the highlands of central Asia and the western Himalayas, is better represented in the central area of this region. The sect. *Lanuginosa* (subg. *Tuberosa*; 10 species) is better represented in the Caucasus and Iranian mountains, but a couple of species reach the western Mediterranean and northern Europe.

Regarding the subg. *Robertium*, it has already been mentioned that sect. *Trilopha* is focused on the Horn of Africa area and the nearby Arabian peninsula, and in southern Iran (five species) plus one species endemic to the Himalayas. The sect. *Polyantha* (seven species) is found throughout the Himalayas reaching Burma and the mountains of western China. One of the two species of sect. *Divaricata* is restricted to the Caucasus and northern Iran while the other is widespread, occurring from western and central Europe to central Asia and the Himalayas. The sect. *Batrachioidea* (four species) is also widespread, occurring from western and central Europe to central Asia and the Himalayas. The sect. *Ruberta* has four species endemic from Macaronesian islands, three endemic from the Mediterranean Basin and the remaining three widespread throughout the Mediterranean Basin, central Europe, Asia and Africa. The native status of *G. robertianum* in northeastern U.S.A. and Japan is controversial (Aedo 2012; Nishida & al. 2012). Finally, the sect. *Unguiculata* has two species restricted to the north side of the Mediterranean Basin.

The sect. *Geranium* is represented in Europe and mainland Asia by 53 native species. This section comprises three species widely distributed through Europe and Asia. Besides, six species are restricted to the mountains of southern Europe and northern Africa and seven more occur also in lowlands of central Europe and extend to Caucasus and West or central Asia. The greatest diversity of section *Geranium* is found in southern China and adjacent areas of the Himalayas with 22 species, and in eastern Siberia and adjacent regions of northeastern China and Korean peninsula with 10 species. Four species extend throughout Siberia, Mongolia and nearby areas and one is restricted to the mountains of south India. The sect. *Dissecta* (four species) is better represented in the eastern Mediterranean Basin, although one species has spread to Macaronesia and northern Europe.

*Geranium* occurs over a broad latitudinal range, from 73°N in Siberia (*G. albiflorum*) to 55°S in the Patagonia (*G. berterioanum* and *G. sessiliflorum*). The northernmost record of *G. sylvaticum* in Spitsbergen (Norway) at 78°N may be a single adventive specimen or a mislabeling. *G. sylvaticum*, is found however, at 71°N in Cape Nord and *G. pratense* in Siberia at 69°N.

Annuals species occur mainly in disturbed areas such as roadsides or fields. Perennial species grow in a diversity of habitats, such as evergreen and deciduous forests, shrublands, grasslands, meadows, cliffs, bogs, dunes and rocky areas; some perennials (e.g., *G. arabicum* or *G. nepalense*) are also common on disturbed areas. The elevation range extends from sea level to 5300 m. *Geranium donianum* was collected in some places of the Himalayas at 5300 m. *Geranium nakaoanum* and *G. saxatile* were collected also in the Himalayas at 5000 m. The other species that reach 5000 m are *G. humboldtii*, *G. maniculatum*, *G. sessiliflorum* and *G. sibbaldioides*, the four from the Andes. Species at low elevations and even sea level occur only in temperate or cold regions, except *G. limae*, which grows at sea level in the coastal deserts of Peru.

## RELATIONSHIPS BASED ON DNA MARKERS AND CLASSIFICATION

Price & Palmer (1993) studied the chloroplast *rbcl* gene sequences to assess the circumscription of Geraniaceae, generic relationships within the family and the affinities of the close families. They found that only *Hypseocharis* receives strong support as close relative of the Geraniaceae core comprising *Erodium*, *Geranium*, *Monsonia*, *Pelargonium* and *Sarcocaulon*. Geraniaceae s.str. is also supported as natural group by the loss of the intron in the plastid gene *rpl16* (Downie & Palmer 1992: 27; Price & al. 1990). According to Price & Palmer (1993) *Geranium* and *Erodium* appear as sister genera. Within *Geranium* the sampling was too small to draw conclusions about the relationships within the genus. These authors only studied six species of *Geranium*, four of them of the subg. *Robertium* that appears as sister group of the remaining two that belong to subg. *Geranium* and subg. *Erodioidea*. Further findings about plastid and mitochondrial genomes of Geraniaceae and its evolutive implications can be found in Palmer & al. (1987), Bakker & al. (2006), and Guisinger & al. (2008, 2011).

The unusual species of Hawaiian *Geranium* (sect. *Neurophyloides*) was analyzed by Pax & al. (1997) using *rbcl* gene sequences. This work, which includes seven of the nine taxa of the section, provides strong support to sect. *Neurophyloides* as a natural group. The sect. *Neurophyloides* is deeply nested within subg. *Geranium* with some species from America as close relatives. The authors indicated that an additional sampling from the American species of subg.

*Geranium* is required to more precisely establish the relationships of this group within the genus.

The nrITS and chloroplast *trnL-trnF* spacers were sequenced for the four species of sect. *Dissecta* (Aedo & al. 2005b). This work provides strong support to sect. *Dissecta* as a natural group. In the study the annual *G. dissectum* appeared as sister to the three perennial remaining species.

Hyeon & Park (2006) studied the relationships of 16 taxa of Korean *Geranium*, all belonging to sect. *Geranium*, using ITS sequences. These authors suggests that all Korean species constitute a “monophyletic group”. This conclusion becomes almost inevitable since no *Geranium* species from other areas was studied. As outgroups they studied species of *Erodium* and *Pelargonium*. It is interesting to note the close relationship suggested to *G. nepalense*, *G. thunbergii*, *G. tripartitum* and *G. wilfordii*, all of them gathered into the *Sibiricum Group* in the present study together with other species from Asia and Oceania.

The nrITS and chloroplast *trnL-trnF* spacers were sequenced to the ten species of sect. *Lanuginosa* [as subsect. *Mediterranea*] by Aedo & al. (2007). This work provides strong support to sect. *Lanuginosa* as a natural group. Two clades are recovered, one including the two annual species and other with the eight perennials, in which *G. tuberosum* (sect. *Tuberosa*) emerges within sect. *Lanuginosa*. Further analyses that include sequences from the remaining six species of sect. *Tuberosa* are needed to elucidate the expected close relationship of both groups.

Fiz & al. (2008) used chloroplast *trnL-trnF* and *rbcl* sequences to explore the relationships of Geraniaceae and Hypseocharitaceae. They include sequences of 42 species of *Geranium*. The clade of the genus *Geranium* showed two main branches, one formed by most species of subg. *Robertium* (except those of sect. *Batrachioidea* and sect. *Divaricata*), and the other formed by subg. *Geranium*, subg. *Erodioidea*, subg. *Tuberosa* and the two previously mentioned sections of subg. *Robertium*. As the authors pointed out, a more extensive sampling is needed to acquire sufficient information for a new taxonomic treatment within the genera *Geranium* and *Erodium*. I regret that the main authors of this article did not listen to my request to carefully review the appendices with the vouchers, which resulted in some errors. The *Alves* 2762 (MA) collection is attributed to *G. brasiliense* in the appendix 1 and to *G. arachnoideum* in the appendix 2; the first is correct. The collection *Aedo* 468 does not exist; it probably corresponds to *Aedo* 4681b, a specimen of *G. divaricatum* from Spain, not from Turkey. *Cousineau* 43581 is a collection of *G. bicknellii* from Canada, not from U.S.A. In other cases it is not possible to trace the vouchers in any herbarium.

Mitchell & al. (2009) studied the relationships of nine native taxa of New Zealand, all belonging to sect. *Geranium*, using ITS and ETS sequences. As outgroups they include species of sect. *Dissecta* (subg. *Geranium*) and sect. *Lanuginosa* (subg. *Tuberosa*). The results shows that the New Zea-

land species are grouped into a well-supported clade. As the authors pointed out, further sampling of Australian and South American related species must be carried out to clarify the relationships of New Zealand cranesbills.

Nishida & al. (2012) carried out a detailed study of *G. robertianum* in Japan using DNA sequences from the plastid regions of the *trnL* intron, *trnL3'-trnF* and *trnH-psbA* intergenic spacer regions, and the nuclear ITS region. They found three major groups and suggested that in Japan there are both indigenous populations and others naturalized from abroad. As the authors pointed out, further sampling from outside of Japan might help to identify the origin of these non-native populations of *G. robertianum*.

Park & al. (2015) studied the evolution of *Geranium* (17 species) mitochondrial genomes in relation to the movement of genetic material between unrelated species or horizontal gene transfer. They found extensive loss of genes and introns in *Geranium* mitochondrial genomes and the presence of foreign DNAs that "is the most extensive of any eudicot examined so far (except holoparasite *Rafflesia*)". The results of this work indicated that "... several *Geranium* species containing foreign organellar DNA from diverse eudicots, including many transfers from parasitic plants". *Geranium brycei* and *G. incanum* have a *cox2* gene that was transferred from *Cuscuta* L., and they have "at least 13 foreign MITPs [mitochondrial DNA of plastid origin] in their mitochondrial genomes".

Wakasugi & al. (2017) carried out a detailed study of *G. yesoense*, an endemic from Japan using DNA sequences of the plastid regions of the *trnL* intron plus *trnL-trnF*, and the nuclear ITS region. Eleven other species of *Geranium* from Japan were added to this study. They analyzed 17 samples of *G. yesoense*, a good sampling of the geographical and morphological variability of this species, concluding that there is no support for recognized subgroups within this species. On the other hand, their results support the close relationship among the species of the *Krameri Group* (*G. krameri*, *G. soboliferum*, *G. yoshinoi*, *G. yesoense*) and those of the *Palustre Group* (*G. shikokianum*). Furthermore, they also found a close relationships among the species of the *Sibiricum Group* (*G. sibiricum*, *G. thunbergii*, *G. tripartitum*, *G. wilfordii*) which was previously described by Woo & Park (2006).

Kurata & al. (2021b) performed a phylogenetic analyses of the eleven native species from Japan using chloroplast genome sequencing and genome-wide single-nucleotide polymorphisms. They results support the close relationship among the species of the *Sibiricum Group* (*G. nepalense*, *G. sibiricum*, *G. thunbergii*, *G. tripartitum*, *G. wilfordii*) and the *Erianthum Group* (*G. erianthum*, *G. reinii*). Furthermore, they obtained a clade that included species of the *Krameri Group* (*G. krameri*, *G. soboliferum*, *G. yoshinoi*, and *G. yesoense*) and the *Palustre Group* (*G. maximowiczii*, *G. shikokianum*). This clade is difficult to interpret because it also includes isolated representatives of other groups from eastern Asia. Ku-

rata & al. (2022) investigated genetic differentiation among populations of *G. erianthum* and related species using chloroplast genome and single-nucleotide polymorphisms. The lack of significant genetic differentiation suggests that the current range of *G. erianthum* resulted from rapid expansion during the last glacial era.

Wondimu & al. (2017) studied the complex of *G. arabicum* and allied species using AFLP markers. They focused their work on alpine populations and they identified only two genetic groups corresponding to *G. arabicum* and *G. kilimandscharicum*.

Esfandani Bozchaloyi & al. (2017a) studied *G. robertianum* in Iran using ISSR markers. A similar work was carried out with *G. dissectum* (Esfandani Bozchaloyi & al. 2017b), *G. purpureum* (Esfandani Bozchaloyi & al. 2017c) and *G. molle* (Esfandani Bozchaloyi & al. 2018a). These authors found some variability in the Iranian samples studied and suggested the existence of ecotypes. Esfandani Bozchaloyi & al. (2017d, 2018b) studied sect. *Batrachioidea* and subg. *Geranium* respectively in order to explore species identification using ISSR markers as well. Their conclusions are limited by a geographical approach, since they only studied Iranian samples of the species of this country.

Marcussen & Meseguer (2017) studied fruit evolution within *Geranium* using all available GenBank sequences (Nov. 2014) of rDNA (i.e., ITS: 143 sequences), the cpDNA regions *rbcl* (172 sequences) and *trnL-trnF* (93 sequences), covering a total of 54 species. They found a clade A contained all taxa with carpel-projection type of fruit, (i.e. subg. *Robertium*, excluding sects. *Batrachioidea* and *Divaricata*), and a clade B where the sect. *Tuberosa* (seed-ejection type without callus nor prong) was recovered as a sister to the rest. As nested sister came a weakly supported clade containing sect. *Subacaulia* (*Erodium*-type), *G. divaricatum* of sect. *Divaricata* (carpel-projection type inoperative), sect. *Erodioidea* (*Erodium*-type), and sect. *Batrachioidea* (carpel-projection type), and a weakly supported clade containing the rest. Within the 'rest clade', a moderately supported subclade, containing sect. *Brasiliensia* (*Erodium*-type) plus sect. *Aculeolata* (*Erodium*-type) plus *G. albanum* of sect. *Divaricata* (carpel-projection type inoperative), was sister to a strongly supported clade consisting of sect. *Dissecta* (seed-ejection type with prong) and the large sect. *Geranium* (seed-ejection type with callus).

According to Marcussen & Meseguer (2017) the infrageneric classification should be accommodate to this structure. As a result, subg. *Robertium* (removing sect. *Batrachioidea* and sect. *Divaricata*) was restricted and subg. *Geranium* including the remaining groups was expanded. These authors, however, indicated that such subg. *Geranium* is "morphologically difficult to characterise", while they proposed a combination of two characters to define the subg. *Robertium*, both partially shared by the subg. *Geranium*.

Marcussen & Meseguer (2017) suggest that *Erodium*-type of seed discharge is ancestral in *Geranium*, as Yeo

(1984) and Nieto Feliner & Aedo (1995) pointed out, and that the other discharge syndromes were derived from it multiple times. These authors considered that “the four extant lineages having retained the *Erodium*-type of seed discharge may be considered relictuous, in terms of being early divergent, geographically confined and species-poor”, and that the “seed-ejection type discharge syndrome might have enhanced diversification in *Geranium*, probably by allowing species to disperse more efficiently into new habitats”. It should be noted, however, that some species with carpel-projection type, such as *G. molle* or *G. pusillum*, have spread with great efficiency as weeds throughout most of the world.

Studies with different DNA markers are providing valuable results to better interpret the evolution of *Geranium* and to accommodate, as much as possible, the infrageneric classification to the evolutionary history of the group. However, the complex evolutionary history of *Geranium*, in which biparental transmission of plastids (Corriveau & Coleman 1988), hybridization (Wilder-Kiefer & Yeo 1987), polyploidy (Van Loon 1984a, 1984b, 1984c; Yeo 1973a, 1984) and horizontal gene transfer (Park & al. 2015) have played an important role, make it very difficult to arrange a consistent and operative infrageneric classification.

In this scenario, some complex morphological structures, such as different types of fruit, could have arisen several times in the course of evolution. But the opposite option seems less expensive in evolutionary terms and as, a consequence, more parsimonious. The contradictions between the different data sets cannot be resolved in favour of the DNA markers in a simplistic way without further evidence, especially considering the limitations of the current available molecular data, in terms of scope and homology, and the way in which they have been analyzed, based on the similarity of extant species.

The redefinition of established infrageneric groups in others with a weak morphological base which lack unique or well-defined characters, and the exclusion or underestimation of important characters difficult to acquire in evolutionary terms, seems undesirable. A new hypothesis has to explain all the known facts better. For these reasons, the infrageneric classification proposed by Yeo, based on morphologically recognizable groups, is maintained in general lines, awaiting a new and operative hypothesis that better explains all the evidence.

I am confident that within sect. *Geranium* there are some groups that reflect trends of variation with some phylogenetic signal and show geographical cohesion that deserve to be recognized, perhaps as sections. However, they have discordant elements, resulting in an unsatisfactory classification. Thus, while a satisfactory solution emerges, it seems useful to join the most similar species into informal groups in order to yield a framework to advance toward a natural classification. Yeo (2002a) realized this problem when he stated that sect. *Geranium* “... needs to be divided up into

smaller groups but at present I do not see how such groups can be defined”. Consequently, Yeo (2002a) proposed to divide sect. *Geranium* into 28 informal groups using the name of one representative species of each group (the *Palustre Group*, the *Refractum Group*, etc.). These groups have been used in this work with some modifications to arrange the species in operative units.

# CONSPECTUS OF CLASSIFICATION

## I. subg. *Erodioidea*

### Ia. sect. *Erodioidea*

1. *G. phaeum*
2. *G. reflexum*
3. *G. aristatum*

### Ib. sect. *Aculeolata*

4. *G. aculeolatum*

### Ic. sect. *Subacaulia*

5. *G. cinereum*
6. *G. subargenteum*
7. *G. dolomiticum*
8. *G. cazorlense*
9. *G. nanum*
10. *G. argenteum*
11. *G. austroapenninum*
12. *G. subcaulescens*
13. *G. thessalum*
14. *G. subacutum*
15. *G. petri-davisi*
16. *G. palmatipartitum*
17. *G. makmelicum*
18. *G. ponticum*
19. *G. lazicum*

### Id. sect. *Brasiliensia*

20. *G. arachnoideum*
21. *G. brasiliense*
22. *G. glanduligerum*

## II. subg. *Geranium*

### Ila. sect. *Geranium*

#### **The Sylvaticum Group**

23. *G. albiflorum*
24. *G. atlanticum*
25. *G. caeruleatum*
26. *G. endressii*
27. *G. pseudosibiricum*
28. *G. rivulare*
29. *G. schmidii*
30. *G. sylvaticum*

#### **The Erianthum Group**

31. *G. erianthum*
32. *G. platyanthum*
33. *G. reinii*

#### **The Pratense Group**

34. *G. collinum*
35. *G. pratense*
36. *G. saxatile*

### **The Wallichianum Group**

37. *G. christensenianum*
38. *G. lambertii*
39. *G. procurrens*

## TAXONOMY

**Geranium** L., Sp. Pl.: 676. 1753; Gen. Pl. ed. 5: 306. 1754.  
TYPE: *G. sylvaticum* L. (designated by Hanks & Small 1907: 4).

Annual, biennial, or perennial herbs, rarely shrubs, usually pubescent. Leaves simple, usually palmatifid or palmatisect, sometimes digitate or entire, rarely peltate, stipulate, petiolate; basal leaves usually forming a rosette; cauline leaves opposite or alternate, rarely verticillate; stipules lanceolate to ovate, entire or multisect. Inflorescence terminal or axillary, cymose, bracteate with the cymules arranged dichasially or monochasially, the cymules sometimes in umbel-like aggregates or on floriferous branchlets (brachyblasts). Flowers usually in cymules 1- or 2-flowered, actinomorphic, rarely somewhat zygomorphic, without hypanthium and without a nectariferous tube. Sepals 5, imbricate, obtuse or mucronate at apex. Petals 5, free, frequently emarginate, sometimes clawed. Stamens 10, in two whorls,

stamens of outer whorl opposite petals, stamens of inner whorl alternate with petals, all bearing anthers or, very rarely, the 5 outer reduced to a short filament; filaments lanceolate, free, glabrous or with eglandular hairs. Nectaries 5, alternating with petals or, rarely, forming a ring all around the flower. Ovary 5-locular, lobed, with 2 superposed ovules per locule, style distinct, diverging into five stigma lobes at the apex. Fruit a long-beaked schizocarp, splitting into five 1-seeded mericarps, with stigma remnants persistent at the apex; rostrum portion of fruit either gradually or abruptly narrowed; mericarp with a basal callus or prong to retain the seed, or retention structure absent, sometimes with a strand of fibers at apex (for type of fruit dispersal and its morphological implications see morphology chapter). Seed ellipsoid, slightly compressed, more or less finely reticulate, with little or no endosperm; embryo with massive induplicate or convoluted cotyledons.

### KEY TO SPECIES OF GERANIUM IN NORTH AND CENTRAL AMERICA (FIG. 5)

1. Annuals, rarely biennials.
  2. Three outer sepals with lengthwise keels and transverse flaps between these, two inner sepals  $\pm$  smooth. **298. *G. lucidum***
  2. All sepals smooth.
    3. Mericarps reticulate or transversely wrinkled. **277. *G. molle***
    4. Leaves palmatifid; petals emarginate. **301. *G. yeoi***
    4. Leaves palmatisect; petals rounded (rarely retuse).
      5. Petals (14.9)16.2-19.3(20.7) mm long; mericarps usually lacking fibers derived from the rostrum and attached near the apex; staminal filaments (8.7)9.6-11.3(12.8) mm long. **301. *G. yeoi***
      5. Petals 5.3-14.2 mm long; mericarps usually with fibers derived from the rostrum and attached near the apex; staminal filaments (3.7)5.2-7.3(8) mm long.
        6. Petals (8.5)10.5-12.5(14.2) mm long, (2.1)2.6-4.5(6.1) mm wide; anthers purple; mericarps reticulate, with few thin ridges and scarcely anastomosing in the basal half but more abundant distally and forming 1-2(3) overlapping, collar-like keels at the apex. **300. *G. robertianum***
        6. Petals (5.3)6.3-8.4(9.9) mm long, (0.8)1.5-2(2.6) mm wide; anthers yellow; mericarps reticulate, with thick ridges dense throughout or sometimes thin and sparse in the basal half and forming 1-4 overlapping collars or contiguous circumferential ridges at apex. **299. *G. purpureum***
  3. Mericarps smooth.
    7. Mericarps with a basal prong, without a callus. **298. *G. dissectum***
    7. Mericarps without a basal prong, usually with a callus.
      8. Mericarps with a basal callus.
        9. Rostrum of fruit with an evident narrowed apex 1.9-6.8 mm long.
          10. Petals (6.4) 7-10.7 mm long; peduncles with retrorse, appressed, eglandular hairs. **63. *G. columbinum***
          10. Petals 3.3-8.7 mm long; peduncles with patent, glandular, and eglandular hairs.
            11. Leaves polygonal in outline, deeply divided (ratio main-sinus length/middle segment length = 0.82-0.95); petals emarginate; mericarps black. **121. *G. bicknellii***
            11. Leaves orbicular in outline, not deeply divided (ratio main-sinus length/middle segment length = 0.51-0.65); petals rounded; mericarps brown. **63. *G. rotundifolium***
        9. Rostrum of fruit with a very short narrowed apex 0.5-2 mm long.
          12. Pedicels with patent, sometimes retrorse (not appressed) eglandular hairs and patent, glandular hairs; mericarps densely hairy, the hairs 0.5-1.9 mm long. **120. *G. carolinianum***

12. Pedicels with retrorse, appressed, eglandular hairs; mericarps sparsely hairy, the hairs 0.2-0.7 mm long. **122. G. texanum**
8. Mericarps without a basal callus
13. Mericarps with appressed hairs covering all the surface. **278. G. pusillum**
13. Mericarps glabrous but densely ciliate at the base. **276. G. aequale**
1. Perennials.
14. Herbs acaulescent.
15. Cymules 1-flowered. **168. G. costaricense**
15. Cymules 2-flowered.
16. Mericarps without basal callus; flowers zygomorphic. **307. G. dalmaticum**
16. Mericarps with basal callus; flowers actinomorphic.
17. Leaves palmatisect; peduncles with antrorse, appressed, eglandular hairs. **155. G. alpicola**
17. Leaves palmatifid; peduncles with patent to retrorse, eglandular hairs and patent, glandular hairs. **138. G. crenatifolium**
14. Herbs with developed aerial stem.
18. Cymules 1-flowered (Note: *G. andicola* and *G. sibiricum* occasionally also with some 2-flowered cymules).
19. Petals hairy on 3/4 of the adaxial surface. **152. G. monanthum**
19. Petals glabrous adaxially, sometimes hairy towards the base.
20. Petals (2.2)4-8.1 mm long.
21. Leaves with the middle segment obtriangular, 3-5(9)-lobed at the apex. **73. G. potentilloides**
21. Leaves with middle segment rhombic, (7)9-14-lobed in the distal half. **67. G. sibiricum**
20. Petals (9.6)10-21.8 mm long.
22. Leaves with middle segment 3-5(7)-lobed in distal half. **89. G. sanguineum**
22. Leaves with middle segment (5)7-14(28)-lobed in distal half.
23. Peduncles (77)90-138(215) mm long; petals white. **142. G. andicola**
23. Peduncles 27-97(115) mm long; petals white or purple.
24. Petals purple; anthers 1.2-1.8 mm long; leaves sericeous abaxially. **140. G. potentillifolium**
24. Petals white; anthers 1.7-2.2 mm long; leaves densely hairy abaxially. **141. G. bellum**
18. Cymules 2-flowered, rarely more.
25. Stipules 2-4-fid, with linear and deep lobes. **233. G. incanum**
25. Stipules entire, sometimes with a very short bifid apex.
26. Mericarps without a basal callus.
27. Mericarps reticulate, glabrous.
28. Petals (18.5)21-22.5(24.2) mm long, glabrous; leaves palmatisect. **304. G. palmatum**
28. Petals (12.4)14-16.7(18.1) mm long, hairy at the base; leaves palmatifid. **307. G. dalmaticum**
27. Mericarps smooth, hairy.
29. Petals 7-11 mm long; rostrum of fruit without narrowed apex. **279. G. pyrenaicum**
29. Petals 15.4-28.4 mm long; rostrum of fruit with a narrowed apex 2.6-6.7 mm long. **270. G. ibericum**
26. Mericarps with a basal callus
30. Petals with a claw 6.1-11.1 mm long. **162. G. unguiculatum**
30. Petals without a claw, or rarely with a short claw 0.8-1.1 mm long.
31. Pedicels and peduncles with antrorse, appressed, eglandular hairs. **155. G. alpicola**
31. Pedicels and peduncles with retrorse to patent hairs.
32. Leaves sericeous on both surfaces. **133. G. niveum**
32. Leaves ± hairy but not sericeous adaxially.
33. Leaves palmatisect.
34. Petals (4.2)5.1-6.4(6.8) mm long. **154. G. cruceroense**
34. Petals 13.4-16.3(17.5) mm long.
35. Inflorescence with glandular hairs. **156. G. madrense**
35. Inflorescence without glandular hairs. **157. G. charucanum**
33. Leaves palmatifid (*G. solanderi* occasionally also palmatisect).
36. Leaves verticillate at basal nodes and opposite towards the apex. **158. G. oaxacanum**
36. Leaves never verticillate.

37. Petals glabrous adaxially or hairy towards the base (usually with short hairs), ciliate at the base.
38. Pedicels with eglandular hairs, without glandular hairs (sometimes with sessile minute glands).
39. Petals (3)4-6(8.5) mm long.
40. Pedicels with retrorse, appressed hairs; sepals accrescent, ovate. **111. *G. core-core***
40. Pedicels with patent to retrorse, not appressed hairs; sepals not accrescent, lanceolate. **102. *G. solanderi***
39. Petals (7.8)9-21(24.1) mm long.
41. Rostrum of fruit with a narrowed apex 4.5-7 mm long; mericarps with glandular hairs 1.1-1.9 mm long. **134. *G. maculatum***
41. Rostrum of fruit with a narrowed apex (1)2.1-4.2 mm long; mericarps without glandular hairs.
42. Sepals glabrous, except for some eglandular hairs on the veins.
43. Petals (7.8)9.2-11 mm long; stem with retrorse, curved, eglandular hairs 0.3-0.6 mm long. **163. *G. durangense***
43. Petals (11.5)13.7-16.1(18.2) mm long; stem with patent, eglandular hairs (0.4)1-1.7 mm long. **144. *G. goldmanii***
42. Sepals hairy abaxially.
44. Petals 18.4-21.4(23.5) mm long, white. **137. *G. lozanoii***
44. Petals (11.5)15.5-17.9(24.1) mm long, usually purple. **143. *G. schiedeanum***
38. Pedicels with glandular hairs.
45. Petals (3.5)4.5-8.3(9.1) mm long; fruits 15.2-26.6 mm long.
46. Petal apex rounded or retuse; mericarps smooth, black or deep brown. **68. *G. thunbergii***
46. Petal apex emarginate; mericarps with one transverse vein at apex, usually brown. **153a. *G. seemannii* subsp. *seemannii***
45. Petals (10)11-24(35) mm long; fruits (19.3)22-52 mm long.
47. Middle cauline leaves alternate, distal cauline leaves opposite; cymules solitary or in aggregates at the apex of each branch.
48. Petals emarginate; stigmatic lobes hairy. **26. *G. endressii***
48. Petals rounded or rarely slightly emarginate at the apex; stigmatic lobes glabrous.
49. Peduncles (105)119-170(235) mm long. **136. *G. mexicanum***
49. Peduncles 11-72(90) mm long.
50. Staminal filaments with eglandular hairs 0.2-0.7 mm long. **30. *G. sylvaticum***
50. Staminal filaments with eglandular hairs 1.2-3.2 mm long.
51. Petioles with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. **31. *G. erianthum***
51. Petioles with patent, eglandular hairs 0.2-1.6 mm long, and, rarely, patent glandular hairs 0.2-0.6 mm long. **159. *G. trolliifolium***
47. Cauline leaves opposite; cymules usually solitary.
52. Nectaries hairy.
53. Fruits 29-37.8 mm long, pointing downward or reflexed when immature; staminal filaments with a broad triangular base. **35. *G. pratense***
53. Fruits 35-52 mm long, erect; staminal filaments lanceolate. **135. *G. oreganum***

52. Nectaries glabrous.
54. Fruits reflexed. **161. G. mooreanum**
54. Fruits erect.
55. Middle and distal cauline leaves hastate in outline. **150. G. lilacinum**
55. Middle and distal cauline leaves polygonal in outline.
56. Staminal filaments 16-24(30) mm long; sepals mucro 3-4.2 mm long; rostrum of fruit with a narrowed apex 15-18.3 mm long. **160. G. campanulatum**
56. Staminal filaments 3.3-12.4 mm long; sepals mucro 0.3-2.2 mm long; rostrum of fruit with a narrowed apex 0.9-6 mm long.
57. Cymules 2-flowered, solitary.
58. Petals 10-13.9 mm long. **153b. G. seemannii** subsp. **repens**
58. Petals 15-20.8 mm long.
59. Staminal filaments with hairs 0.5-1.5(2.2) mm long; stem with glandular hairs 0.1-0.5 mm long. **138. G. crenatifolium**
59. Staminal filaments with hairs 1.1-2.8 mm long; stem without glandular hairs. **139. G. pringlei**
57. Cymules 2-6-flowered, solitary or in aggregates at the apex of each branch.
60. Peduncles (105)119-170(235) mm long; staminal filaments with hairs 0.4-0.8 mm long. **136. G. mexicanum**
60. Peduncles 16-72(90) mm long; staminal filaments with hairs (1.2) 1.5-2.8 mm long. **159. G. trolliifolium**
37. Petals hairy on (1/5)1/3-3/4 of the adaxial surface, usually with long hairs.
61. Inflorescence monochasially branched, with cymules borne singly at the nodes along the stem.
62. Herbs prostrate to ascending, rooting at nodes. **151. G. hintonii**
62. Herbs erect or prostrate to ascending but not rooting at nodes.
63. Petals 14-16.8(17.2) mm long; sepals mucro (2.6)2.8-4.8 mm long; pedicels only with eglandular hairs; peduncles (67)111-222(240) mm long. **145. G. hernandesii**
63. Petals (6.1)7-12 (13.9) mm long; sepals mucro (0.6)1.2-1.7(2.5) mm long; pedicels usually with glandular hairs; peduncles (12)21-73(89) mm long.
64. Petals (6.1)7.2-8.4 (9.8) mm long.
65. Rostrum of fruit without a narrowed apex; middle segment of the leaves 7.9-12.9(15.3) mm wide at the base. **149. G. hystricinum**
65. Rostrum of fruit with a narrowed apex 1.7-3.2 mm long; middle segment of the leaves (14.6) 17.3-25.4 mm wide at the base. **148. G. latilobum**
64. Petals (8)9.2-12.3(13.9) mm long.
66. Petals white to pink, hairy on 1/2-3/4 of the adaxial surface, basally ciliate on the margin, with hairs 0.7-1.6 mm long; stem and leaves usually with only eglandular hairs. **146. G. deltoideum**

66. Petals purple, hairy on 1/4-1/3 of the adaxial surface, basally ciliate on the margin, with hairs 0.3-0.7 mm long; stems and leaves with glandular hairs. **147. *G. gentryi***
61. Inflorescence dichasially branched, with terminal cymules.
67. One (rarely two) alternate cauline leaf between the base and the first branch point; staminal filaments with hairs (0.7)1.3-1.6 (2) mm long; nectaries with a tuft of hairs covering the entire surface. **130. *G. latum***
67. Leaves all opposite; staminal filaments with hairs 0.2-1(1.2) mm long (if longer, then nectaries with a tuft of hairs at the apex, adaxially glabrous); nectaries glabrous to hairy.
68. Petals reflexed. **125. *G. dodecatheoides***
68. Petals patent to erect patent.
69. Nectaries glabrous or with a tuft of hairs at the apex and adaxially glabrous.
70. Petals 5-9(10.5) mm long; sepals 5.4-6.5(8) mm long. **126. *G. lentum***
70. Petals (10)11-20 mm long; sepals (6.9) 8-11 mm long.
71. Stigmatic remnants 3-6(6.8) mm long; basal leaves (7.1)10-16 cm wide. **129. *G. viscosissimum***
71. Stigmatic remnants (4)6-8 mm long; basal leaves 2.4-7.3 cm wide.
72. Peduncles (8)18-120(170) mm long; pedicels 18-33(49) mm long; fruits 22-31 (36) mm long; rostrum of fruit with a narrowed apex 2-3.8 mm long. **123. *G. caespitosum***
72. Peduncles (22)82-190(310) mm long; pedicels (17)44-86 mm long; fruits (29)32-42 mm long; rostrum of fruit with a narrowed apex (2.9)4-6.1 mm long. **124. *G. californicum***
69. Nectaries adaxially hairy, sometimes with short hairs.
73. Petals 12.1-20 mm long.
74. Petals purple; leaves 2.2-3.5 cm long, with the middle segment 5-7-lobed in distal half; stigmatic remnants 2.1-2.2 mm long. **132. *G. potosinum***
74. Petals white; leaves (3.9)4.5-10.5 cm long with the middle segment 6-11(16)-lobed in distal half; stigmatic remnants 3-4.2 mm long. **128. *G. richardsonii***
73. Petals 6-11(13.1) mm long.
75. Stem with patent to retrorse, appressed, eglandular hairs 0.3-1.2 mm long; leaves 2.9-6.6(8) cm long, with the middle segment 5-15-lobed in distal half. **127. *G. wislizeni***
75. Stem with retrorse, appressed eglandular hairs 0.3-0.5 mm long; leaves 2-3.2 cm long with the middle segment 3-7-lobed in distal half. **131. *G. tenue***

#### KEY TO SPECIES OF GERANIUM IN SOUTH AMERICA

1. Annuals, rarely biennials.
2. Fertile stamens 5 (external whorl lacking anthers). **278. *G. pusillum***
2. Fertile stamens 10.
3. Mericarps reticulate or transversely wrinkled.
4. Leaves palmatifid; petals emarginate. **277. *G. molle***
4. Leaves palmatisect; petals entire, rarely retuse.

5. Petals (8.5)10.5-12.5(14.2) mm long, (2.1)2.6-4.5(6.1) mm wide; anthers purple; mericarps reticulate, with few thin ridges and scarcely anastomosing in the basal half but more abundant distally and forming 1-2(3) overlapping, collar-like keels at the apex. **300. G. robertianum**
5. Petals (5.3)6.3-8.4(9.9) mm long, (0.8)1.5-2(2.6) mm wide; anthers yellow; mericarps reticulate, with thick ridges dense throughout or sometimes thin and sparse in the basal half and forming 1-4 overlapping collars or contiguous circumferential ridges at apex. **299. G. purpureum**
3. Mericarps smooth.
6. Mericarps glabrous over most of the surface, densely ciliate at the base. **276. G. aequale**
6. Mericarps hairy over most of the surface. **258. G. dissectum**
7. Mericarps with a basal prong, without a basal callus. **121. G. bicknellii**
7. Mericarps without a basal prong, with a basal callus. **120. G. carolinianum**
8. Rostrum of fruit with an evident narrowed apex 2-5.6 mm long.
8. Rostrum of fruit with a short narrowed apex 0.5-2 mm long.
1. Perennials.
9. Leaves with an abscission zone between lamina and petiole.
10. Leaves lanceolate, entire, with marginal cilia; pedicels without glandular hairs. **225. G. exallum**
10. Leaves obtriangular, tridentate at the apex, glabrous; pedicels usually with glandular hairs. **226. G. jahnii**
9. Leaves without an abscission zone between lamina and petiole.
11. Small shrubs.
12. Cymules 1-flowered; pedicels without glandular hairs. **166. G. loxense**
12. Cymules 2-flowered; pedicels with glandular hairs.
13. Petals 10-14.2 mm long, dark purple; sepals mucro 0.6-1.5 mm long; stipules lanceolate. **221. G. lignosum**
13. Petals (11.2)13.1-19.3 mm long, purple; sepals mucro (1.2)1.7-2.2 mm long; stipules lanceolate with a setaceous apex 1.9-7.7 mm long. **218. G. lindenianum**
11. Herbs.
14. Cymules 1-flowered.
15. At dispersal, mericarps propelled with enclosed seed and attached awn (*Erodium*-type discharge).
16. Mericarps with a basal beak 0.8-0.9 mm long; peduncles and pedicels without glandular hairs. **20. G. arachnoideum**
16. Mericarps with a basal beak 0.2-0.4 mm long; peduncles and pedicels with glandular hairs.
17. Petals glabrous adaxially; basal leaves without glandular hairs abaxially. **21. G. brasiliense**
17. Petals hairy on the basal 1/4 of the adaxial surface; basal leaves with glandular hairs abaxially. **22. G. glanduligerum**
15. At dispersal, each single seed is launched from mericarp by the explosive recurvature of the awn (seed-ejection type discharge), while the awn and the mericarp wall remain attached to the columella.
18. Herbs scapiform (usually cushion-like), sometimes with more or less developed internodes covered by stipules.
19. Leaves sericeous, at least adaxially.
20. Leaves sericeous adaxially, glabrous abaxially. **177. G. humboldtii**
20. Leaves sericeous on both surfaces.
21. Leaves digitate, with 3-5 segments (lateral segments turned upward).
22. Petioles with patent to retrorse hairs; rostrum of fruit with a narrowed apex 1.6-2 mm long. **184. G. digitatum**
22. Petioles with antrorse hairs; rostrum of fruit without a narrowed apex. **185. G. trujillense**
21. Leaves palmatifid to palmatisect (lateral segments plane or turned downward).
23. Leaves palmatisect.
24. Petioles with antrorse hairs.
25. Petals 4-7.4 mm long; nectaries glabrous; rostrum of fruit without narrowed apex. **189. G. tovarii**
25. Petals 10.6-15 mm long; nectaries hairy; rostrum of fruit with a narrowed apex 1-1.7 mm long. **190. G. weddellii**

24. Petioles with patent or retrorse hairs.  
 26. Leaves 0.4-0.8 cm long; petioles with retrorse,  $\pm$  appressed hairs 0.2-1 mm long; sepals 4.1-8.2 mm long. **175. *G. ecuadoriense***  
 26. Leaves 0.9-1.7 cm long; petioles with patent to retrorse (not appressed) hairs 0.8-1.6 mm long; sepals 7-9 mm long. **188. *G. sericeum***
23. Leaves palmatifid.  
 27. Leaves 0.3-0.9 cm long; peduncle hairs 0.1-0.4(0.6) mm long. **183. *G. planum***  
 28. Sepals without mucro; petals 6-7 mm long. **182. *G. crassipes***  
 28. Sepals mucro 0.2-0.6 mm long; petals 5.2-10.5 mm long.  
 27. Leaves 0.7-1.4 cm long; peduncle hairs 0.4-1.5 mm long.  
 29. Middle and usually lateral leaf segments 3-lobed; rostrum of fruit without narrowed apex. **187. *G. ruizii***  
 29. Middle and lateral leaf segments entire; rostrum of fruit with a narrowed apex. **186. *G. nivale***
19. Leaves glabrous to densely hairy, never sericeous.  
 30. Leaves entire with tridentate apex, the middle segment 1(3)-lobed at the apex; petals slightly emarginate. **164. *G. azorelloides***  
 30. Leaves tripartite, digitate, palmatifid, or palmatisect; petals usually rounded at apex.  
 31. Leaves tripartite. **169. *G. campii***  
 31. Leaves digitate, palmatifid, or palmatisect.  
 32. Leaves digitate, with 3-5 segments (lateral segments turned upward).  
 33. Leaves glabrous or with antrorse cilia on the margin, and with the middle segment entire. **171. *G. maniculatum***  
 33. Leaves with patent cilia on the margin and with the middle segment (2)3-lobed. **170. *G. rhomboidale***
32. Leaves palmatifid or palmatisect (lateral segments plane or turned downward).  
 34. Leaves palmatisect.  
 35. Petioles with retrorse, appressed hairs; nectaries hairy; rostrum of fruit with a narrowed apex 1 mm long. **178. *G. macbridei***  
 35. Petioles with patent hairs (sometimes glabrous); nectaries glabrous; rostrum of fruit without narrowed apex. **176. *G. multipartitum***
34. Leaves palmatifid.  
 36. Stipules scarious, stramineous, obtuse (with a setaceous apex). **174. *G. stramineum***  
 36. Stipules papery, brown or reddish, lanceolate (sometimes with a setaceous apex).  
 37. Rootstock vertical, turnip-shaped.  
 38. Petals (9.5)11.5-15.7 mm long, hairy on margin and base of abaxial surface; nectaries hairy; rostrum of fruit with a narrowed apex 0.7-1.5 mm long. **119. *G. parodii***  
 38. Petals (4.5)6-12.8 mm long, glabrous (rarely with a few cilia on the basal margin); nectaries glabrous; rostrum of fruit without narrowed apex. **118. *G. sessiliflorum***
37. Rootstock not turnip-shaped.  
 39. Petioles with antrorse hairs. **180. *G. jaekelae***  
 39. Petioles with patent to retrorse hairs.  
 40. Cymules (1.9)2.6-4.2 times as long as adjacent leaves. **167. *G. alonsoi***  
 40. Cymules (0.5)0.7-1.8 times as long as adjacent leaves.  
 41. Leaves  $\pm$  hairy on one or both surfaces.  
 42. Stipules ending in 1-3 bristles 0.2-0.6 mm long; leaves with the middle segment lanceolate, sometimes obtriangular. **165c. *G. sibbaldioides* subsp. *elongatum***  
 42. Stipules not ending in bristles; leaves with the middle segment broadly obovate. **181. *G. pavonianum***

41. Leaves glabrous, except on the margins.  
 43. Leaves with the middle segment entire, sometimes with a lateral tooth. **165a. G. siboldioides** subsp. **siboldioides**  
 43. Leaves with the middle segment 3(4)-lobed at apex.  
 44. Petioles with patent, eglandular hairs 0.2-0.7 mm long. **172. G. foreroi**  
 44. Petioles with retrorse, appressed, eglandular hairs 0.1-0.5 mm long.  
 45. Sepals mucro (0.6)0.7-0.8(1.2) mm long; petals (7.8)10.1-11.5(13.2) mm long, usually glabrous. **165b. G. siboldioides** subsp. **beckianum**  
 45. Sepals mucro 0.3-0.7 mm long; petals 10.5-21 mm long.  
 46. Petals hairy on both surfaces, mainly at the base of adaxial surface; nectaries glabrous. **173. G. paludosum**  
 46. Petals glabrous; nectaries hairy. **179. G. sagasteguii**  
 18. Herbs with developed aerial stems, sometimes prostrate but the internodes not covered by stipules.  
 47. At least some cymules arising from the rootstock; sepals usually with patent hairs 0.9-2.8 mm long on margin.  
 48. Petals (9.5)11.5-15.7 mm long, hairy on margin and base of abaxial surface; nectaries hairy; rostrum of fruit with a narrowed apex 0.7-1.5 mm long. **119. G. parodii**  
 48. Petals (4.5)6-12.8 mm long, glabrous (rarely with a few cilia at the basal margin); nectaries glabrous; rostrum of fruit without narrowed apex. **118. G. sessiliflorum**  
 47. All cymules borne on aerial stems; sepals without long patent hairs on margin.  
 49. Herbs erect; leaves (1.5)3-5.6(8.5) cm long.  
 50. Seeds hairy; pedicels sometimes with glandular hairs. **204. G. rupicola**  
 50. Seeds glabrous; pedicels without glandular hairs. **206. G. leucanthum**  
 49. Herbs usually prostrate to ascending; leaves (0.5)1-4(7.3) cm long.  
 51. Cymules with peduncles, pedicels and 2 bracteoles, and leaves deeply divided (ratio main-sinus length/middle segment length = 0.63-0.90).  
 52. Petals (6.2)7.8-11.3(16.3) mm long. **202. G. laxicaule**  
 52. Petals (4.4)5-5.6(6.3) mm long. **66. G. nepalense**  
 51. Cymules without pedicels and bracteoles, or leaves little divided [ratio main-sinus length/middle segment length = (0.49)0.56-0.64(0.69)].  
 53. Petals (8.4)10-14(15.4) mm long and leaves not deeply divided (except in *G. ayacuchense*); fruits (11.8)12-22(25) mm long.  
 54. Leaves deeply divided [ratio main-sinus length/middle segment length = (0.68)0.72-0.86]. **203. G. ayacuchense**  
 54. Leaves not deeply divided [ratio main-sinus length/middle segment length = (0.38)0.52-0.64(0.69)].  
 55. Leaves hairy on nerves abaxially and on margin. **197. G. renifolium**  
 55. Leaves hairy on both surfaces.  
 56. Mericarps without glandular hairs; peduncles usually without glandular hairs. **199. G. peruvianum**  
 56. Mericarps with glandular hairs; peduncles with glandular hairs.  
 57. Leaves polygonal in outline, (1.7)1.8-3.1(3.4) cm long. **198. G. stuebelii**  
 57. Leaves orbicular in outline, 1.3-2.1 cm long. **200. G. comarapense**  
 53. Petals (3.9)5.2-7.2(12.4) mm long and leaves deeply divided; fruits 6.4-15(21) mm long.  
 58. Petioles and peduncles with glandular hairs.  
 59. Fruits 17-21 mm long; rostrum of fruit with a narrowed apex 1.1-2.1 mm long; stem ascending or climbing 26-100(200) cm long. **201. G. chilloense**

59. Fruits 6.4-11.2 mm long; rostrum of fruit without narrowed apex; stem prostrate 2.8-17 cm long.
60. Leaves  $\pm$  divided [ratio secondary sinus length/middle segment length = (0.31)0.44-0.52(0.61)], with appressed, eglandular hairs restricted to margins and nerves of abaxial surface, sometimes also adaxially. **192. *G. pseudodiffusum***
60. Leaves not deeply divided [ratio secondary sinus length/middle segment length = (0.20)0.25-0.31(0.36)], with patent, eglandular hairs on both surfaces. **193. *G. antisanae***
58. Petioles and peduncles without glandular hairs. **194. *G. ayavacense***
61. Leaves palmatisect. **196. *G. reptans***
61. Leaves palmatifid. **205. *G. soratae***
62. Petioles and peduncles with patent hairs. **195. *G. smithianum***
62. Petioles and peduncles with retrorse, appressed hairs. **191. *G. diffusum***
63. Stem erect; leaves with the middle segment 6-9-lobed.
63. Stem prostrate to ascending; leaves with the middle segment (1)3-5(6)-lobed.
64. Leaves with the middle segment 5(6)-lobed.
64. Leaves with the middle segment (1)3(5)-lobed.
14. Cymules 2-flowered.
65. Mature leaves lanuginous abaxially. **222. *G. matucanense***
66. Petals (14.1)20-22(27.2) mm long; rostrum of fruit with a narrowed apex 6.3-8.5 mm long; sepals and pedicels without glandular hairs.
66. Petals 9.8-14.1 mm long; rostrum of fruit with a narrowed apex 1.2-2 mm long; sepals and pedicels with glandular hairs.
67. Stem with patent, eglandular hairs; cauline leaves always petiolate. **224. *G. paramicola***
67. Stem with retrorse, appressed, eglandular hairs; cauline leaves usually sessile. **223. *G. mutisii***
65. Mature leaves  $\pm$  hairy abaxially.
68. Inflorescence branched dichasially.
69. Pedicels without glandular hairs.
70. Leaves digitate (lateral segments upward); rostrum of fruit with a narrowed apex. **208. *G. cavanillesii***
70. Leaves palmatifid, sometimes with the base broadly cuneate; rostrum of fruit usually without narrowed apex.
71. Leaves with the middle segment entire, broadly lanceolate; rostrum of fruit with a narrowed apex 0.9-1.9 mm long. **211. *G. jaramilloi***
71. Leaves with the middle segment 3(5)-lobed, obtriangular; rostrum of fruit without narrowed apex.
72. Leaves with antrorse, appressed cilia on the margin, giving a scarios aspect; basal leaves cordate; petals ciliate on the basal margin. **210. *G. santanderiense***
72. Leaves with patent cilia or glabrous on the margin; basal leaves usually subtruncate or cuneate; petals usually glabrous.
73. Basal leaves coriaceous, with 3(5) segments, subtruncate, with some eglandular hairs at the apex of each segment and near the margin (sometimes with patent cilia). **209. *G. lainzii***
73. Basal leaves not coriaceous, with (3)5 segments, usually broadly cuneate to subtruncate, with patent eglandular hairs on the margin. **207. *G. multiceps***
69. Pedicels with glandular hairs 0.2-1.7 mm long (rarely without glandular hairs, then leaves velutinous abaxially and fruits reflexed).
74. Vegetative stems  $\pm$  horizontal, covered with imbricate stipules, usually without petiole remnants. **216. *G. holosericeum***
74. Vegetative stems absent.
75. Petals (12.8)14.8-18.8 mm long. **217. *G. schultzei***
75. Petals 6-12.5 mm long.

76. Petioles of basal leaves densely covered by patent hairs, eglandular hairs 0.5-2.5 mm long and glandular hairs 0.3-0.5 mm long. **212. G. sebosum**
76. Petioles of basal leaves only with eglandular hairs 0.1-0.9 mm long.
77. Stolons present; leaves 1.6-2.7 cm long, with a middle segment 3-lobed. **213. G. stoloniferum**
77. Stolon absent; leaves (1.9)3.6-5.8 cm long, with a middle segment (3)5-13-lobed.
78. Fruits reflexed. **214. G. velutinum**
78. Fruits erect. **215. G. subnudicaule**
68. Inflorescence branched monochasially.
79. Herbs prostrate to ascending, rooting at nodes; leaves subtomentose in bud.
80. Leaves with the middle segment (3)5-9(15)-lobed; basal and middle peduncles (25)57-91(125) mm long; petals (7.5)9.1-10.4(11.4) mm long. **219. G. killipii**
80. Leaves with the middle segment 3-5(7)-lobed; basal and middle peduncles (16)37-59(92) mm long; petals (5.6)6.3-8.5(9.3) mm long. **220. G. meridense**
79. Herbs usually erect but sometimes ascending, not rooting at nodes (except *G. seemannii* subsp. *seemannii* and *G. thunbergii* trailing to ascending, and sometimes rooting at the nodes); leaves not subtomentose in bud.
81. Petals (11.4)13.4-16.4(16.9) mm long, glabrous, rarely with a few cilia on the basal margin; rostrum of fruit with a narrowed apex (2)2.3-3.8(5) mm long. **112. G. tablasense**
81. Petals (3.1)5-8(14.3) mm long, ciliate on the basal margin or sometimes on the base of the adaxial surface; rostrum of fruit with a narrowed apex (0)1-2(2.9) mm long, in some species lacking.
82. Peduncles (59)82-151(251) mm long. **113. G. venturianum**
82. Peduncles (3.6)16-65(139) mm long.
83. Peduncles with glandular hairs.
84. Leaves with the middle segment rhombic; rostrum of fruit with a narrow apex (0)1-2(2.9) mm long.
85. Sepals (3.4)4.3-5.3(7.3) mm long. **153a. G. seemannii** subsp. *seemannii*
85. Sepals (5.1)5.4-6.5(8.2) mm long.
86. Herbs erect or ascending, not rooting at nodes; roots thickened; petals glabrous on the base of the adaxial surface and ciliate on the basal margin. **114. G. fallax**
86. Herbs trailing and ascending, sometimes rooting at nodes; roots not thickened; petals hairy on the base of the adaxial surface and on the basal margin. **68. G. thunbergii**
84. Leaves with the middle segment obtriangular; rostrum of fruit without narrowed apex.
87. Basal leaves deeply divided with narrow lobes [ratio secondary sinus length/middle segment length = (0.25)0.40-0.53(0.62)]; petals (7)7.9-10.2(14) mm long. **110. G. skottsbergii**
87. Basal leaves not deeply divided [ratio secondary sinus length/middle segment length = (0.13)0.24-0.38(0.42)]; petals (5.1)6.5-8(9) mm long. **106. G. berteroanum**
83. Peduncles without glandular hairs.
88. Herbs ascending (not rooting at nodes); cymules at the basal part of the stem usually 1-flowered (some arising directly from the rootstock), cymules of the distal part 2-flowered. **109. G. magellanicum**
88. Herbs usually erect to ascending; cymules always 2-flowered and arising along leafy stems.
89. Basal leaves deeply divided with narrow lobes [ratio secondary sinus length/middle segment length = (0.25)0.40-0.53(0.62)]; petals (7)7.9-10.2(14) mm long. **110. G. skottsbergii**

89. Basal leaves not deeply divided [ratio secondary sinus length/middle segment length = (0.13)0.21-0.41(0.42)]; petals (3.1)3.5-7.5(9) mm long.

90. Pedicels with retrorse-appressed hairs.

**111. *G. core-core***

90. Pedicels with patent hairs.

91. Petals (4)4.5-5.1(6.1) mm long; leaves with the middle segment rhombic.

**108. *G. albicans***

91. Petals (5)5.6-8(9) mm long; leaves with the middle segment obtriangular.

92. Leaves with moderately wide middle segment at the base [ratio segment width at the base/middle segment length = (0.20)0.24-0.32(0.42)]; nectaries usually hairy; sepals mucro (0.2)0.3-0.4(0.5) mm long.

**107. *G. limae***

92. Leaves with a more narrow middle segment at the base [ratio segment width at the base/middle segment length = (0.11)0.17-0.22(0.31)]; nectaries glabrous; sepals mucro (0.3)0.6-0.8(0.9) mm long.

**106. *G. berterioanum***

#### KEY TO THE SPECIES OF GERANIUM IN THE PACIFIC AREA

1. Annuals, rarely biennials.

2. Fertile stamens 5 (external whorl lacking anthers).

**278. *G. pusillum***

2. Fertile stamens 10.

3. The three outer sepals with lengthwise keels and transverse flaps between these, the two inner  $\pm$  smooth.

**298. *G. lucidum***

3. All sepals smooth

4. Mericarps reticulate or transversely wrinkled.

5. Leaves palmatifid; petals emarginate.

**277. *G. molle***

5. Leaves palmatisect; petals rounded (rarely retuse).

6. Petals (14.9)16.2-19.3(20.7) mm long; mericarps usually lacking fibers derived from the rostrum and attached near the apex; staminal filaments (8.7)9.6-11.3(12.8) mm long.

**301. *G. yeoi***

6. Petals 5.3-14.2 mm long; mericarps usually with fibers derived from the rostrum and attached near the apex; staminal filaments (3.7)5.2-7.3(8) mm long.

7. Petals (8.5)10.5-12.5(14.2) mm long, (2.1)2.6-4.5(6.1) mm wide; anthers purple; mericarps reticulate, with few thin ridges and scarcely anastomosing in the basal half but more abundant distally and forming 1-2(3) overlapping, collar-like keels at the apex.

**300. *G. robertianum***

7. Petals (5.3)6.3-8.4(9.9) mm long, (0.8)1.5-2(2.6) mm wide; anthers yellow; mericarps reticulate, with thick ridges dense throughout or sometimes thin and sparse in the basal half and forming 1-4 overlapping collars or contiguous circumferential ridges at apex.

**299. *G. purpureum***

4. Mericarps smooth.

8. Mericarps with a basal prong, without a basal callus.

**258. *G. dissectum***

8. Mericarps without a basal prong, usually with a basal callus.

9. Mericarps glabrous over most of the surface, densely ciliate at base, without a basal callus.

**276. *G. aequale***

9. Mericarps hairy over most of the surface, with a basal callus.

10. Cauline leaves uniformly opposite; rostrum of fruit with a narrowed apex 1.9-4.2 mm long.

**87. *G. rotundifolium***

10. Cauline leaves alternate in middle of shoot but becoming opposite toward the apex; rostrum of fruit with a narrowed apex 0.5-2 mm long.

**120. *G. carolinianum***

1. Perennial herbs or shrubs [Note: *G. yeoi*, a biennial, is included again here, because the life-form of robust specimens may be difficult to determine.]

11. Petioles with an abscission zone at base; stipules connate at the base, sheathing; small shrubs.

12. Corolla zygomorphic; petals reddish; sepals (10.5)11-12.1(13.5) mm long; rostrum of fruit with narrowed apex 12.8-16.1 mm long. **227. G. arboreum**
12. Corolla actinomorphic; petals white, sometimes with purplish veins; sepals 4.7-9(11.8) mm long; rostrum of fruit with a narrowed apex 0.4-2.9 mm long.
13. Leaves ovate to elliptic, rarely obovate, with (1)4-14 teeth on each side, usually serrate almost to base (but at least 1/3 from apex). **228. G. multiflorum**
13. Leaves obtriangular-cuneiform, rarely elliptic or obovate, with 3-7 teeth near the apex.
14. Leaves sericeous on both surfaces.
15. Leaves predominantly tridentate at apex. **229d. G. cuneatum** subsp. **tridens**
15. Leaves predominantly 5-7-toothed at apex.
16. Peduncles (11)17.7-20.6(25.9) mm long; ascending shrubs rooting at nodes. **230. G. hanaense**
16. Peduncles (3.3)4-7(9.4) mm long; erect shrubs not rooting at nodes. **229b. G. cuneatum** subsp. **hololeucum**
14. Leaves glabrous except for a line of silky appressed hairs on the nerves of both surfaces, or sericeous only on the abaxial surface.
17. Leaves usually glabrous except for a line of silky, appressed hairs on the nerves on both surfaces, rarely with sparse hairs between nerves. **229a. G. cuneatum** subsp. **cuneatum**
17. Leaves sericeous on abaxial surface.
18. Peduncles (14.1)21-28(33.4) mm long. **232. G. kauaiense**
18. Peduncles 3.1-11(13.3) mm long.
19. Erect shrubs, not rooting at nodes; inflorescence with cymules grouped in (3)7-15-flowered cymes at ends of brachyblasts; petals (7.7)9-10(11.7) mm long. **229c. G. cuneatum** subsp. **hypoleucum**
19. Ascending shrubs, often rooting at nodes; inflorescence with cymules grouped in 2-5-flowered cymes at ends of brachyblasts; petals (9.5)12-15.5(17.6) mm long. **231. G. hillebrandii**
11. Petioles without an abscission zone at base; stipules free or connate, sometimes overlapping but not sheathing; herbs.
20. Mericarps without a basal callus.
21. Leaves palmatifid; petals 7-11 mm long, emarginate. **279. G. pyrenaicum**
21. Leaves palmatisect; petals (14.9)16-20(22.5) mm long, rounded at the apex.
22. Leaves (16)20-30(45) cm long; petals (8.5)11.4-14.5(19.9) mm wide, with claw 0.8-3.1 mm long. **303. G. maderense**
22. Leaves (5)6.1-11.7(18.8) cm long; petals (4.6)6.5-8.3(9.4) mm wide, with claw 5.8-8.1 mm long. **301. G. yeoi**
20. Mericarps with a basal callus.
23. Cymules 2-flowered.
24. Stipules 2-4-fid, with linear and deep lobes. **233. G. incanum**
24. Stipules ovate to lanceolate, entire, sometimes with a very short bifid apex.
25. Petals patent to subreflexed; at dispersal, mericarp propelled with enclosed seed and attached awn (*Erodium*-type discharge). **1. G. phaeum**
25. Petals erect-patent; at dispersal, each single seed is launched from mericarp by the explosive recurvature of the awn (seed-ejection type discharge), while the awn and the mericarp wall remain attached to the columella.
26. Leaves palmatisect.
27. Rootstock short, vertical,  $\pm$  cylindrical, not turnip-shaped; leaves with 3 segments. **70. G. tripartitum**
27. Rootstock turnip-shaped; leaves with 5 segments.
28. Hairs of pedicels retrorsely appressed. **105. G. retrorsum**
28. Hairs of pedicels patent to retrorse but not appressed. **102. G. solanderi**
26. Leaves palmatifid.
29. Hairs of staminal filaments 1.4-4.2 mm long; rostrum of fruit with a narrowed apex 5-11.4 mm long.
30. Hairs of stem and petioles retrorse-appressed, eglandular; leaves deeply divided [ratio main-sinus length/middle segment length = (0.80)0.82-0.91]. **31. G. erianthum**

30. Hairs of stem and petioles, patent, eglandular and usually glandular as well; leaves moderately divided [ratio main-sinus length/middle segment length = 0.63-0.71(0.81)]. **33. *G. reinii***
29. Hairs of staminal filaments 0.1-0.8 mm long; rostrum of fruit with a narrowed apex 0.5-5.5 mm long or abruptly ending in the stigmatic remnants, without any narrowing of the apex.
31. Leaves with 3(5) segments. **69. *G. wilfordii***
31. Leaves with 5(9) segments.
32. Petals (2.8)4-8(9.2) mm long; anthers 0.3-1.1 mm long.
33. Rootstock turnip-shaped.
34. Hairs of pedicels retrorsely appressed. **105. *G. retrorsum***
34. Hairs of pedicels patent to retrorse but not appressed. **102. *G. solanderi***
33. Rootstock more or less cylindrical, not turnip-shaped.
35. Sepals with glandular hairs; petals (6.8)7.3-8.3(9) mm long. **68. *G. thunbergii***
35. Sepals without glandular hairs; petals (2.8)3.3-5.6(7.8) mm long.
36. Rostrum of fruit with a narrowed apex 0.9-2 mm long; sepals (4.1)4.4-5.5(5.8) mm long; petals (4.4)5-5.6(6.3) mm long. **66. *G. nepalense***
36. Rostrum of fruit abruptly ending on the stigmatic remnants, without narrowed apex; sepals (2.8)3.5-4.2(5.7) mm long; petals (2.8)3.3-4.7(7.8) mm long. **75. *G. homeanum***
32. Petals (9.7)11-18 (25.1) mm long; anthers 1.2-3.1 mm long.
37. Petals glabrous on both surfaces, ciliate on basal margin and sometimes with some hairs on base of adaxial surface.
38. Stipules connate, broadly ovate.
39. Petals rounded at the apex; staminal filaments white. **55. *G. shikokianum***
39. Petals emarginate; staminal filaments black at least at tip. **40. *G. wallichianum***
38. Stipules free, lanceolate.
40. Staminal filaments lanceolate with a broad triangular base and an abruptly narrowed apex; nectaries hairy. **35. *G. pratense***
40. Staminal filaments lanceolate; nectaries glabrous.
41. Petals 11.3-13.2(14.6) mm long, rounded at the apex. **104. *G. grande***
41. Petals (16.1)18.3-23.9(25.1) mm long, emarginate. **26. *G. endressii***
37. Petals hairy on 1/4-1/2 of adaxial surface and on basal margin.
42. Petals (13.2)14-18(20) mm long.
43. Sepals with minute, antrorse, appressed hairs 0.2-0.3 mm long; stigmatic remnants (5)5.6-6.4(6.7) mm long; nectaries with a tuft of hairs at apex. **59. *G. soboliferum***
43. Sepals with ± erect-patent hairs 0.3-1.7 mm long; stigmatic remnants (3.3)3.6-3.9(4.3) mm long; nectaries usually glabrous. **62. *G. yesoense***
42. Petals (9.7)11-13.5(14.6) mm long.
44. Stigmatic remnants (3.6)3.8-4.3(4.6) mm long; sepals 6.2-7.4(7.8) mm long; leaves with the middle segment (7.1)8.1-11.4(15.5) mm wide at base. **61. *G. yoshinoi***
44. Stigmatic remnants (4.5)5.6-6.2(6.6) mm long; sepals (6.2)7.4-9.1(10) mm long; leaves with the middle segment (4.3)5.4-8.5(8.8) mm wide at base. **58. *G. krameri***
23. Cymules usually 1-flowered.
45. Herbs acaulescent.
46. Leaves with the middle segment elliptic to obovate, usually entire. **117. *G. cruentum***
46. Leaves with the middle segment obtriangular, with 3-7 lobes in distal half.
47. Pedicels with antrorse hairs; leaves with the base cuneate to subtruncate (with basal leaf segments patent or oriented upward). **115. *G. antrorsum***
47. Pedicels with patent to retrorse hairs; leaves with the base cordate (with basal leaf segments oriented downward). **116. *G. brevicaule***
45. Herbs caulescent.

48. Petals emarginate; anthers (1.3)1.7-2.7(2.8) mm long. **89. *G. sanguineum***
48. Petals rounded or slightly emarginate at the apex; anthers 0.5-1.6(2.1) mm long.
49. Petals (12.1)14.1-18.4(20.5) mm long; stipules connate, 2.9-6.6 mm wide, broadly ovate. **60. *G. hayatanum***
49. Petals (2.2)5-12(15.9) mm long; stipules usually free, 0.2-2.6(4.3) mm wide, lanceolate or ovate.
50. Petals (5.2)7-12(15.9) mm long.
51. Stem erect, not rooting at nodes; leaves silky-hairy on both surfaces; petals with claw 1-2.6 mm long. **76. *G. traversii***
51. Stem prostrate to ascending, usually rooting at nodes; leaves  $\pm$  hairy on both surfaces; petals without claw.
52. Leaves (0.6)0.7-0.9(1.3) cm long. **98. *G. papuanum***
52. Leaves (1.1)2.2-3.7(5.2) cm long.
53. Petals (9)10.8-13.6(15.6) mm long; peduncles (27)57-93(205) mm long. **77. *G. neglectum***
53. Petals (5.2)7.2-8.4(12.7) mm long; peduncles (25)37-50(72) mm long. **71. *G. suzukii***
50. Petals 2.2-6(8.1) mm long.
54. Leaves palmatisect. **93. *G. castroviejoi***
55. Sepals with both eglandular and glandular hairs.
55. Sepals with only eglandular hairs.
56. Leaves with 7(9) segments, the pair of basal segments  $\pm$  perpendicular to the plane formed by remaining segments; middle segment 9-12-lobed in distal half, 0.2-0.3 mm wide at base, with linear lobes. **91. *G. leptodactylon***
56. Leaves (3)5 segments, all arranged in the same plane; middle segment 3-4(6)-lobed in distal half, (0.3)0.6-1.3 mm wide at base, with lanceolate lobes. **92. *G. clemensiae***
54. Leaves palmatifid. **94. *G. monticola***
57. Leaves sericeous abaxially.
57. Leaves  $\pm$  densely hairy or strigose abaxially. **95. *G. wilhelminae***
58. Hairs of sepals patent, glandular; stipules ovate.
58. Hairs of sepals eglandular, rarely with glandular hairs but then stipules lanceolate.
59. Leaves with the middle segment entire.
60. Peduncles 12.1-17.7 mm long; leaves sparsely strigose adaxially. **97. *G. editum***
60. Peduncles 1.7-5.1 mm long; leaves glabrous adaxially. **96. *G. hyperacrium***
59. Leaves with the middle segment 3-14-lobed in distal half.
61. Peduncles 1.5-5(9) mm long. **100. *G. balgooyi***
61. Peduncles (1.5)6.5-35(83) mm long.
62. Rootstock turnip-shaped; sepals mucro 0.1-0.2(0.3) mm long. **103. *G. obtusisepalum***
62. Rootstock not turnip-shaped; sepals mucro (0.2)0.5-1 (1.6) mm long.
63. Leaves (0.6)1.2-3(3.8) cm long, with the middle segment 3-5(9)-lobed, obtriangular.
64. Sepals (5.4)6.6-7.4(7.9) mm long. **74. *G. ardjunense***
64. Sepals (2.9) 3.6-5(6.2) mm long.
65. Leaves with the adaxial surface glabrous or with scattered long hairs; ratio main-sinus length/middle segment length = 0.62-0.70(0.76). **99. *G. whartonianum***
65. Leaves with the adaxial surface pilose or strigose; ratio main-sinus length/middle segment length = (0.65)0.73-0.81(0.84).

66. Rostrum of fruit with a narrowed apex 0.7-0.9(1) mm long; sepals mucro (0.6)1-1.1 mm long. **72. *G. frigidurbis***
66. Rostrum of fruit without a narrowed apex or with a narrowed apex 0.4-0.5(1) mm long; sepals mucro (0.3)0.5-0.7(1.2) mm long.
67. Leaves with the middle segment 3-5(9)-lobed; bracteoles (0.2)0.4-0.5(0.6) mm wide. **73. *G. potentilloides***
67. Leaves with the middle segment 3-lobed; bracteoles (0.5)0.7-1(1.5)mm wide. **101. *G. niuginiense***
63. Leaves (1.7)2.9-5.1(5.8) cm long, with the middle segment (6)9-14-lobed, rhombic.
68. Leaves with the middle segment narrowly rhombic; sepals mucro (0.9)1-1.5(1.6) mm long [ratio mucro length/sepal length = (0.18)0.23-0.28(0.35)]. **67. *G. sibiricum***
68. Leaves with the middle segment broadly rhombic; sepals mucro (0.4)0.7-0.9(1) mm long [ratio mucro length/sepal length = (0.10)0.15-0.20(0.23)]. **66. *G. nepalense***

#### KEY TO THE SPECIES OF GERANIUM IN EURASIA AND AFRICA

1. Stem and inflorescence armed with prickles. **4. *G. aculeolatum***
1. Stem and inflorescence without prickles.
2. At dispersal, mericarp propelled with enclosed seed and attached awn (*Erodium*-type discharge).
3. Petals patent or reflexed, obtuse or mucronate at apex; inflorescence with glandular hairs; stems tall (20-80 cm), always erect.
4. Petals patent to subreflexed, 6-8(9) mm wide. **1. *G. phaeum***
4. Petals reflexed, 3.5-6.5 mm wide.
5. Sepals mucro 0.3-0.5 mm long; mericarps 4.5-5 mm long; cauline leaves alternate. **2. *G. reflexum***
5. Sepals mucro 4-5(7) mm long; mericarps 7-8.5 mm long; cauline leaves opposite. **3. *G. aristatum***
3. Petals erect-patent, emarginate or obtuse at apex; inflorescence without glandular hairs; stems short, usually prostrate (except in *G. petri-davisii*).
6. Leaves with the middle segment entire or 2(3)-lobed.
7. Sepals 9-12 mm long, with  $\pm$  patent hairs 0.7-1.7 mm long on the margins; petioles with patent hairs. **16. *G. palmatipartitum***
7. Sepal 8-9(10) mm long, with appressed hairs 0.2-0.4 mm long only; petioles with appressed hairs. **13. *G. thessalum***
6. Leaves with the middle segment 3-9-lobed.
8. Leaves with the middle segment 3-lobed, rarely some leaves with more.
9. Stems 30-50 cm,  $\pm$  erect; lower cauline leaves alternate; terminal cymules 2-3, crowded and umbel-like. **15. *G. petri-davisii***
9. Stems up to 35 cm, prostrate; cauline leaves, if present, all opposite; terminal cymules solitary.
10. Leaves palmatisect, sericeous on both surfaces. **10. *G. argenteum***
10. Leaves palmatifid,  $\pm$  pilose, sometimes sericeous below.
11. Petals with a very dark basal spot; staminal filaments and stigma very dark purple. **12. *G. subcaulescens***
11. Petals without basal spot; staminal filaments usually white or  $\pm$  yellow.
12. Herbs 1-5.5 cm high; peduncles 1-10 mm long, sometimes absent; leaves 0.8-1(2.6) cm long, 0.8-1(2.5) cm wide. **9. *G. nanum***
12. Herbs (1)5-35 cm high; peduncles 20-120 mm long; leaves 0.9-3.4 cm long, 0.9-3.6 cm wide.
13. Expanded base of external staminal filaments with aurides. **8. *G. cazorlense***
13. Expanded base of external staminal filaments without auricles.
14. Petioles with scattered retrorse hairs. **5. *G. cinereum***

- 14. Petioles pilose, the hairs mostly patent.
  - 15. Staminal filaments purple. **11. G. austroapenninum**
  - 15. Staminal filaments yellow.
    - 16. Sepals mucro 0.3-2 mm long; anthers very dark purple. **14. G. subacutum**
    - 16. Sepals mucro (0)0.1-0.3 mm long; anthers dark yellow. **17. G. makmelicum**
- 8. Leaves with the middle segment usually 5-9-lobed.
  - 17. Staminal filaments very dark purple; petals with a dark basal spot; leaves glabrous on the abaxial surface, except on veins. **18. G. ponticum**
  - 17. Staminal filaments yellow or deep purple; petals without a basal spot; leaves pilose to sericeous.
    - 18. Leaves pilose on both surfaces.
      - 19. Staminal filaments yellow. **7. G. dolomiticum**
      - 19. Staminal filaments purple. **11. G. austroapenninum**
    - 18. Leaves pilose on the adaxial surface and sericeous on the abaxial surface, the abaxial surface paler.
      - 20. Sepals 7-8 mm long; petals 12-15 mm long, slightly emarginate; mericarps with a long basal beak, 0.7-0.8 mm long. **19. G. lazicum**
      - 20. Sepals 8-11.5 mm long; petals 15-18 mm long, emarginate; mericarps with a short basal beak, 0.2-0.6 mm long. **6. G. subargenteum**
- 2. At dispersal, seed ejected from mericarp (seed-ejection type) or the mericarp, containing the seed, ejected from the plant (carpel-projection type).
  - 21. At dispersal, the whole mericarp, containing the seed, is ejected by the propelling force of the explosive recurvature of the awn, while the awn remains attached to the columella (carpel-projection type) [Note: in *G. albanum* and *G. divaricatum* the rostrum of fruit is not well developed (0.4-0.6 mm wide at the base), and thus the mericarp including the seed is shortly ejected].
  - 22. Leaves palmatisect.
  - 23. Annuals or biennials.
    - 24. Petals (14.9)16.2-19.3(20.7) mm long; mericarps usually lacking fibers derived from the rostrum and attached near the apex; staminal filaments (8.7)9.6-11.3(12.8) mm long. **301. G. yeoi**
    - 24. Petals 5.3-14.2 mm long; mericarps usually with fibers derived from the rostrum and attached near the apex; staminal filaments (3.7)5.2-7.3(8) mm long.
      - 25. Petals (8.5)10.5-12.5(14.2) mm long, (2.1)2.6-4.5(6.1) mm wide; anthers purple; mericarps reticulate, with few thin ridges and scarcely anastomosing in the basal half but more abundant distally and forming 1-2(3) overlapping, collar-like keels at the apex. **300. G. robertianum**
      - 25. Petals (5.3)6.3-8.4(9.9) mm long, (0.8)1.5-2(2.6) mm wide; anthers yellow; mericarps reticulate, with thick ridges dense throughout or sometimes thin and sparse in the basal half and forming 1-4 overlapping collars or contiguous circumferential ridges at apex. **299. G. purpureum**
  - 23. Perennials.
    - 26. Leaves with the middle segment 12-31-lobed in distal half; fruits (14.3)15-17(20.3) mm long; sepals (4.8)5.3-6.2(6.3) mm long. **302. G. cataractarum**
    - 26. Leaves with the middle segment (33)100-260(460)-lobed in distal half; fruits (26)29-38(41) mm long; sepals (5.1)6-8.8(10.5) mm long.
      - 27. Rostrum of fruit hairy on the narrowed apex, with eglandular hairs only; petals (2.8)5.4-5.9(6.4) mm wide. **305. G. reuteri**
      - 27. Rostrum of fruit hairy on the narrowed apex, with eglandular and glandular hairs; petals (8.5)10-14(19.9) mm wide.
        - 28. Staminal filaments (12.7)15.4-16.6(19) mm long, much longer than the sepals; rostrum of fruit with a narrowed apex (10.4)12.1-14.6(16) mm long. **304. G. palmatum**
        - 28. Staminal filaments (5.5)7.8-9(10.3) mm long, not or shortly exerted; rostrum of fruit with a narrowed apex (6.2)7-7.8(9.4) mm long. **303. G. maderense**
  - 22. Leaves palmatifid.

29. Rostrum of fruit very thin (0.4-0.6 mm wide at the base), not developed and thus the discharge mechanism inoperative.
30. Perennials; petals 12-14 mm long; mericarps with a longitudinal crest. **280. *G. albanum***
30. Annuals; petals 4-6.5 mm long; mericarps without a longitudinal crest. **281. *G. divaricatum***
29. Rostrum of fruit well developed and thus the discharge mechanism operative.
31. Annuals; petals (1.6)2-9.7(11.7) mm long.
32. The three outer sepals with lengthwise keels and transverse flaps between these, the two inner  $\pm$  smooth. **298. *G. lucidum***
32. Sepals all smooth.
33. Fertile stamens 5 (external whorl lacking anthers). **278. *G. pusillum***
33. Fertile stamens 10.
34. Petals emarginate; rostrum of fruit not twisted.
35. Mericarps transversely wrinkled. **277. *G. molle***
35. Mericarps smooth. **276. *G. aequale***
34. Petals with rounded apex; rostrum of fruit twisted distally.
36. Mericarps with two longitudinal toothed wings bent dorsally to form a trough-like structure.
37. Mericarps with two horns at apex. **284. *G. biuncinatum***
37. Mericarps without horns.
38. Petals (8.8)9-9.8(11.2) mm long; mericarps with an evident ridge in the middle, protruding beyond the trough-like structure. **282. *G. trilophum***
38. Petals (4.8)6.1-8.1(8.7) mm long; mericarps with a small ridge in the middle, not protruding beyond the trough-like structure. **283. *G. yemense***
36. Mericarps without wings.
39. Mericarps transversely wrinkled with slightly prominent ribs.
40. Ribs of mericarps 8-14, 0.2-0.3 mm apart, glabrous. **287. *G. ocellatum***
40. Ribs of mericarps 4-6, 0.3-0.4 mm apart, with appressed, eglandular hairs 0.1 mm long, mainly on the ribs. **288. *G. brevipes***
39. Mericarps transversely wrinkled with prominent ribs.
41. Leaves deeply palmatifid [ratio main-sinus length/middle segment length = (0.80)0.86-0.89(0.90)]; petals without a basal spot. **285. *G. favosum***
41. Leaves palmatifid [ratio main-sinus length/middle segment length = (0.63)0.66-0.74(0.81)]; petals usually with a dark basal spot. **286. *G. mascatense***
31. Perennials; petals (8.6)13-15(18.8) mm long.
42. Flowers zygomorphic.
43. Basal leaves (4.4)5.2-8.7(10.8) cm long, with the middle segment (8)10-34-lobed in distal half; sepals mucro (1.4)2-3.2(4.2) mm long. **306. *G. macrorrhizum***
43. Basal leaves (2)2.1-3.2(3.6) cm long, with the middle segment 3-5(6)-lobed in distal half; sepals mucro (0.9)1.1-1.6(1.7) mm long. **307. *G. dalmaticum***
42. Flowers actinomorphic.
44. Sepal with longitudinal ribs; petal claw bicarinate.
45. Stem glabrous. **296. *G. glaberrimum***
45. Stem densely hairy. **297. *G. lasiopus***
44. Sepal smooth; petals without claw.
46. Petals emarginate; mericarps smooth. **279. *G. pyrenaicum***
46. Petals rounded or slightly emarginate; mericarps reticulate.
47. Cymules in umbel-like aggregates at the top of each branch.
48. Cymules 2(3)-flowered, in dense umbel-like aggregates at apex of each branch, usually without pedicels; rostrum of fruit without narrowed apex (sometimes up to 0.8 mm); petals (7.8)9.3-11.8(14.1) mm long. **292. *G. polyanthes***
48. Cymules (2)3-flowered, in loose umbel-like aggregates at apex of each branch with well developed peduncles and pedicels; rostrum of fruit with a narrowed apex 2-2.1 mm; petals (13.1)13.8-15.2(16.8) mm long. **294. *G. umbelliforme***

47. Cymules solitary.
49. Cymules 1(2)-flowered; stem glabrous. **291. *G. nakaoanum***
49. Cymules 2-flowered; stem  $\pm$  hairy.
50. Basal cauline leaves alternate. **290. *G. moupinense***
50. Basal cauline leaves opposite.
51. Leaves deeply divided [ratio main-sinus length/middle segment length = (0.70)0.80-0.86(0.89)]. **293. *G. strictipes***
51. Leaves moderately divided [ratio main-sinus length/middle segment length = (0.55)0.68-0.77(0.81)].
52. Petals (8.6)9-9.8(10.6) mm long; nectaries hairy at the top; sepals mucro 0.8-2.4 mm long; leaves with the middle segment 9-16-lobed. **289. *G. hispidissimum***
52. Petals 12.6-13.4 mm long; nectaries glabrous; sepals mucro 1.1-1.2 mm long; leaves with the middle segment 7-8-lobed. **295. *G. wardii***
21. At dispersal, each single seed is launched from mericarp by the explosive recurvature of the awn, while the awn and the mericarp wall remain attached to the columella (seed-ejection type).
53. Mericarps without basal callus.
54. Mericarps not compressed at the apex and with a basal prong; rostrum of fruit not twisted.
55. Annuals; leaves deeply palmatifid [ratio main-sinus length/middle segment length = 0.78-0.88(0.94)]; petals 2.9-5.8 mm long. **258. *G. dissectum***
55. Perennials; leaves palmatifid (ratio main-sinus length/middle segment length = 0.52-0.74); petals 8.5-16.5 mm long.
56. Rootstock  $\pm$  vertical, slender,  $\pm$  turnip shaped, without thickened roots; petals 3.5-4.8 mm wide; pedicels with glandular hairs 1-1.7 mm long. **257. *G. sintenisii***
56. Rootstock oblique, bearing thickened roots; petals (5.8)6-9.4 mm wide; pedicels with or without glandular hairs.
57. Stem with retrorse, eglandular hairs, without glandular hairs, or also with short glandular hairs 0.2-1 mm long. **255. *G. asphodeloides***
57. Stem with glandular hairs 0.6-2.1 mm long. **256. *G. crenophilum***
54. Mericarps longitudinally compressed at the apex and without basal prong; rostrum of fruit twisted.
58. Rootstock not tuberose; leaves palmatifid.
59. Annuals.
60. Seeds brown, mottled; cotyledons with a notch on each side; petals with ciliae at the apex; nectaries with a tuft of hairs at the top. **266. *G. bohemicum***
60. Seeds uniformly brownish red; cotyledons entire; petals glabrous at the apex; nectaries glabrous. **267. *G. lanuginosum***
59. Perennials.
61. Leaves reticulate. **269. *G. renardii***
61. Leaves without reticulate nervation.
62. Pedicels bearing only eglandular hairs.
63. Leaves deeply palmatifid [ratio main-sinus length/middle segment length = 0.71-0.84(0.9)]; stems and petioles glabrous or with sparse eglandular hairs. **275. *G. kurdicum***
63. Leaves moderately palmatifid [ratio main-sinus length/middle segment length = (0.49)0.55-0.65(0.76)]; stem and petioles usually hairy.
64. Peduncles with uncinat eglandular hairs 0.1-0.3 mm long, without long patent hairs. **274. *G. gymnocaulon***
64. Peduncles with uncinat eglandular hairs 0.1-0.3 mm long and patent eglandular hairs 0.4-3.3 mm long.
65. Peduncles with patent, eglandular hairs 0.4-0.7(0.8) mm long; petals (10.4)12.9-16.9(18.3) mm long; leaves with the middle segment (8)9-13(16)-lobed. **273. *G. libani***

65. Peduncles with patent, eglandular hairs (1)2.1-2.5(3.3) mm long; petals (15.4)19.5-24.9(28.4) mm long; leaves with the middle segment (14)16-24(39)-lobed. **270. *G. ibericum***
62. Pedicels bearing glandular and eglandular hairs.
66. Leaves with short secondary lobes (ratio secondary sinus length/middle segment length = 0.04-0.09); petals 5.4-10.6 mm width. **268. *G. gracile***
66. Leaves with deeper secondary lobes (ratio secondary sinus length/middle segment length = 0.15-0.35); petals 9.5-22.5 mm width.
67. Peduncles with patent eglandular hairs 0.6-1(1.2) mm long; petals hairy on the base of abaxial surface, glabrous on the adaxial surface, ciliate on the basal margin. **272. *G. peloponnesiacum***
67. Peduncles with patent eglandular hairs (1)2.3-3.1(4.8) mm long; petals glabrous on both surfaces, ciliate on the basal margin.
68. Leaves with the middle segment rhombic [ratio maximum width/middle segment length = (0.58)0.61-0.68(0.74)]; bracteoles (3.2)5.2-6.4(8.2) mm length. **270. *G. ibericum***
68. Leaves with the middle  $\pm$  obtriangular [ratio maximum width/middle segment length = (0.75)0.76-0.79(0.84)]; bracteoles (8.4)9.6-14.1(18.8) mm length. **271. *G. platypetalum***
58. Rootstock tuberose; leaves  $\pm$  palmatisect.
69. Rootstock vertical of closely superimposed tubercles; basal leaves always absent at flowering time.
70. Leaves with 9-13 segments, in more than 1 plane; middle segment with 6-12 lobes; pedicels usually with glandular hairs. **259a. *G. kotschyi* subsp. *kotschyi***
70. Leaves with 5-7(9) segments, in 1 plane; middle segment with (1)3-7 lobes; pedicels usually without glandular hairs. **259b. *G. kotschyi* subsp. *charlesii***
69. Rootstock horizontal of usually  $\pm$  distant tubercles; basal leaves usually present at flowering time.
71. Pedicels with glandular hairs.
72. Stem with an opposite pair of cauline leaves below the first bifurcation. **262. *G. macrostylum***
72. Stem with 1-2(3) alternate cauline leaves below the first bifurcation. **264. *G. tuberaria***
71. Pedicels without glandular hairs.
73. Sepals (6.7)7.5-9.1 mm long; petals (10.3)16.5-19.3(21) mm long; tubercles fusiform (ratio tubercle width/tubercle length = 0.3-0.5). **263. *G. malviflorum***
73. Sepals 4.2-6.5(7.3) mm long; petals 6.9-14(17.1) mm long; tubercles subglobose (ratio tubercle width/tubercle length = (0.5)0.7-1.3).
74. Stem with 1(2) alternate cauline leaves below the first bifurcation. **261. *G. linearilobum***
74. Stem naked or with an opposite pair of leaves below the first bifurcation.
75. Stem below the first bifurcation naked. **265. *G. tuberosum***
75. Stem bearing a pair of opposite cauline leaves below the first bifurcation.
76. Rostrum of fruit with a narrowed apex (2.1)2.4-3.2 mm long; non-tuberous separations between tubercles (1.7)2.2-5.2 mm wide. **260. *G. libanoticum***
76. Rostrum of fruit with a narrowed apex 0.2-0.5(2.1) mm long; non-tuberous separations between tubercles 0.6-2.2(2.7) mm wide. **265. *G. tuberosum***
53. Mericarps with basal callus.
77. Stipules entire, sometimes with a very short bifid apex.
78. Annuals.
79. Leaves palmatisect or deeply palmatifid; pedicels with only eglandular hairs.
80. Peduncles and pedicels with retrorse eglandular hairs; rostrum of fruit 15-19 mm long, with a 4-6.8 mm long narrowed apex. **63. *G. columbinum***
80. Peduncles and pedicels with antrorse eglandular hairs; rostrum of fruit 9-12 mm long, with a 1-2.1 mm long narrowed apex. **64. *G. schrenkianum***

79. Leaves palmatifid; pedicels usually with eglandular and glandular hairs.
81. Rostrum of fruit with a very short narrowed apex 0.5-2 mm long.
82. Pedicels with patent, sometimes retrorse (not appressed) eglandular hairs and patent, glandular hairs; mericarps densely hairy, the hairs 0.5-1.9 mm long. **120. G. carolinianum**
82. Pedicels with retrorse, appressed, eglandular hairs; mericarps sparsely hairy, the hairs 0.2-0.7 mm long. **122. G. texanum**
81. Rostrum of fruit with an evident narrowed apex, 1.9-5.6 mm long.
83. Leaves polygonal in outline, deeply divided (ratio main-sinus length/middle segment length = 0.82-0.95); petals emarginate; mericarps blackish. **121. G. bicknellii**
83. Leaves orbicular in outline, moderately divided (ratio main-sinus length/middle segment length = 0.51-0.65); petals rounded at apex; mericarps brownish. **87. G. rotundifolium**
78. Perennials.
84. Cymules usually with 1 flower.
85. Petals (12.3)13-17(21.8) mm long.
86. Stipules free or connate at the base; anthers (1.3)1.7-2.7(2.8) mm long; petals emarginate. **89. G. sanguineum**
86. Stipules connate; anthers 1-1.2(1.3) mm long; petals rounded. **81. G. andringitrense**
85. Petals (3.9)4-9(12.4) mm long.
87. Stipules connate.
88. Leaves orbicular in outline, with the middle segment obtriangular, 3-5(7)-lobed in distal half. **83. G. kilimandscharicum**
88. Leaves polygonal in outline, with the middle segment rhombic, (7)11-15(19)-lobed in distal half. **82. G. arabicum**
87. Stipules free.
89. Leaves with the middle segment narrowly rhombic; sepals mucro (0.9)1-1.5(1.6) mm long [ratio mucro length/sepal length = (0.18)0.23-0.28(0.35)]. **67. G. sibiricum**
89. Leaves with the middle segment broadly rhombic; sepals mucro (0.4)0.7-0.9(1) mm long [ratio mucro length/sepal length = (0.10)0.15-0.20(0.23)]. **66. G. nepalense**
84. Cymules usually with 2 flowers.
90. Petals reflexed.
91. Nectary forming a ring around flower; petals sparsely hairy on the basal margin. **45. G. sinense**
91. Nectaries 5, hemispheric, separate; petals with a dense tuft of hairs on the basal margin.
92. Pedicels with dense and purple glandular hairs. **43. G. refractum**
92. Pedicels with glandular hairs colourless, dense to sparse, or absent.
93. Petals with hairs only on basal margin. **44. G. shensianum**
93. Petals with hairs on basal margin and inside base.
94. Staminal filaments almost glabrous or with a few 0.3-0.8(1.1) mm hairs; petals (6.1)8-11(12.3) mm, blackish red to pink with an evident whitish basal zone. **41. G. delavayi**
94. Staminal filaments base with numerous 1-1.8 mm hairs; petals (9.5)11.7-13.9(16.7) mm, white to pink or purple without a whitish basal zone. **42. G. pogonanthum**
90. Petals erect-patent.
95. Rootstock tuberose with subglobose tubercles connected by thin non-tuberous separations; cauline leaves alternate.
96. Petals 8.4-11.9 mm long; sepals 5.3-6.3 mm long. **47. G. canopurpureum**
96. Petals (15.5)15.8-17.2(18.2) mm long; sepals (6.9)7.8-9.6(11.1) mm long. **51. G. pylzowianum**
95. Rootstock without tubercles; cauline leaves opposite or alternate.

97. Cauline leaves alternate (upper usually opposite).
98. Staminal filaments with hairs 1.5-3.2 mm long; rostrum of fruit with a narrowed apex more than 4.8-9.8 mm long.
99. Stem and petioles with retrorse appressed hairs; leaves deeply divided [ratio main-sinus length/middle segment length = (0.80)0.82-0.91]. **31. *G. erianthum***
99. Stem and petioles with patent hairs; leaves moderately divided [ratio main-sinus length/middle segment length = 0.60-0.75(0.78)]. **32. *G. platyanthum***
98. Staminal filaments with hairs 0.2-0.7(2.5) mm long; rostrum of fruit with a narrowed apex 0.5-5(8.5) mm long.
100. Leaves with 3(5) segments; petals 4-6.2(9.2) mm long. **69. *G. wilfordii***
100. Leaves with 5(7) segments; petals (7.2)10-23(27) mm long.
101. Leaves moderately divided [ratio main-sinus length/middle segment length = (0.62)0.79-0.86(0.89)]; glandular hairs on peduncles and pedicels usually present.
102. Petals hairy on 1/4-1/2 of their adaxial and abaxial surfaces, ciliate on the basal margin; glandular hairs on peduncles and pedicels absent. **84. *G. franchetii***
102. Petals hairy on the base of the adaxial surface, glabrous on the abaxial surface, ciliate on the basal margin; glandular hairs on peduncles and pedicels usually present.
103. Stigma dark purple; nectaries with a tuft of hairs at the apex. **88. *G. rubifolium***
103. Stigma pale pink to purple; nectaries glabrous.
104. Stigmatic remnants with hairy lobes; petals (16.1)18.3-23.9(25.1) mm long; cymules solitary. **26. *G. endressii***
104. Stigmatic remnants glabrous; petals (8.1)10-17(19.3) mm long; cymules solitary or in aggregates at the top of each branch.
105. Petals (8.1)10.2-12.7(13.2) mm long, (3.7)4.4-5.8(7.5) mm wide, usually white and emarginated; sepals (4)4.7-6(7.1) mm long. **23. *G. albiflorum***
105. Petals (12.2)13-17.6(19.3) mm long, (6.3)7-10.8(12.6) mm wide, usually purple and rounded; sepals (6.7)7.2-8.6(9.6) mm long. **30. *G. sylvaticum***
101. Leaves deeply divided [ratio main-sinus length/middle segment length = (0.73)0.89-0.93(0.97)]; glandular hairs on peduncles and pedicels usually absent.
106. Sepals (4)4.9-5.6(6.8) mm long; sepals mucro (0.4)0.7-1.1(1.6) mm long. **27. *G. pseudosibiricum***
106. Sepals (5.4)6.5-9(10.9) mm long; sepals mucro (0.7)1-2(2.6) mm long.
107. Petals (7.2)9.9-11.5(15.8) mm long, white; anthers (1.2)1.4-1.6(1.7) mm long. **28. *G. rivulare***
107. Petals (11.7)13-20(21.1) mm long, purple; anthers (1.6)1.7-1.8(2.5) mm long.
108. Nectaries with a tuft of hairs at the top; rootstock with napiform roots; leaves with the middle segment (25)38-73(96)-lobed in distal half. **24. *G. atlanticum***
108. Nectaries glabrous; rootstock with thickened roots; leaves with the middle segment (6)9-18(34) lobed in distal half.
109. Petals apices rounded; sepals (5.9)6.5-7.7(8.3) mm long. **25. *G. caeruleatum***

109. Petal apices emarginate; sepals (8)8.1-9.6(9.8) mm long. **29. G. schmidii**
97. Cauline leaves opposite.
110. Petals 3.1-8(12.4) mm long; anthers 0.3-1.2 mm long.
111. Stipules broadly ovate, connate for most of their length. **82. G. arabicum**
111. Stipules lanceolate, free.
112. Sepals with glandular hairs; petals (6.8)7.3-8.3(9) mm long. **68. G. thunbergii**
112. Sepals without glandular hairs; petals (3.1)4.1-6(7.1) mm long.
113. Sepals not accrescent; pedicels with patent to retrorse eglandular hairs. **66. G. nepalense**
113. Sepals accrescent; pedicels with retrorse, appressed eglandular hairs. **111. G. core-core**
110. Petals (7.9)10-20(27.7) mm long; anthers (0.9)1.4-3.1 mm long.
114. Staminal filaments with a broad triangular base and an abruptly narrowed apex.
115. Immature fruits erect. **34. G. collinum**
115. Immature fruits reflexed.
116. Leaves (4.2)7-10.6(16.5) cm long, deeply divided [ratio main-sinus length/middle segment length = (0.81)0.87-0.91(0.94)]; sepals mucro (1.7)2.3-3.1(4.3) mm long. **35. G. pratense**
116. Leaves (1.4)3-4.4(6.2) cm long, moderately divided [ratio main-sinus length/middle segment length = (0.63)0.76-0.83(0.89)]; sepals mucro (0.6)0.9-1.6(2.5) mm long. **36. G. saxatile**
114. Staminal filaments lanceolate or sometime with a slightly dilated at base.
117. Petals with a black basal spot.
118. Petals (11.8)13.1-15.1(19.7) mm long; stipules broadly lanceolate, some free and some partially connate. **39. G. procurrens**
118. Petals (14.9)17-20.1(20.7) mm long; stipules lanceolate, all free. **85. G. psilostemon**
117. Petals without a black basal spot.
119. Staminal filaments black.
120. Stipules broadly ovate, connate for most of their length. **40. G. wallichianum**
120. Stipules lanceolate, free.
121. Petals 12.3-13.6(16) mm long; staminal filaments with 0.2-0.8 mm hairs long. **37. G. christensenianum**
121. Petals (20.4)21.9-24.3(25.4) mm long; staminal filaments covered densely with hairs 1.1-2.2 mm long. **38. G. lambertii**
119. Staminal filaments white to purple.
122. Stipules broadly ovate, connate for most of their length.
123. Leaves deeply divided [ratio main-sinus length/middle segment length = (0.74)0.79-0.84(0.87)]. **55. G. shikokianum**
123. Leaves shallowly divided [ratio main-sinus length/middle segment length = (0.65)0.72-0.79(0.80)]. **52. G. koreanum**
122. Stipules lanceolate or broadly lanceolate, free or sometimes connate for part of their length.
124. Dwarf alpine herbs 4-20(35) cm tall; stipules free.
125. Rootstock with several napiform roots clustered round it; leaves with glandular hairs abaxially. **50. G. napuligerum**
125. Rootstock without napiform roots clustered round it; leaves without glandular hairs.

126. Petals very pale pink, claw 2.3-6.1 mm long, apex rounded. **49. G. farreri**
126. Petals deep purple, without a claw, apex usually emarginate. **48. G. donianum**
124. Herbs (12)50-129 cm tall; stipules connate or free.
127. Petal apices emarginate.
128. Petals (8.3)8.4-9.7(12.2) mm long. **65. G. arnottianum**
128. Petals (11.1)13-25.1 mm long.
129. Leaves with the middle segment (25)38-73(96)-lobed in distal half; rootstock with napiform roots. **24. G. atlanticum**
129. Leaves with the middle segment (9)11-25(41)-lobed in distal half; rootstock without thickened roots.
130. Leaves with an ovate middle segment; ratio secondary sinus length/middle segment length = (0.05)0.06-0.11(0.17).
131. Pedicels with patent, eglandular hairs 0.4-1 mm long, and patent, glandular hairs 0.1 mm long. **80. G. versicolor**
131. Pedicels with retrorse, appressed or hook-shaped, eglandular hairs 0.1-0.3 mm long. **78. G. nodosum**
130. Leaves with a rhombic middle segment; ratio secondary sinus length/middle segment length = (0.14)0.17-0.26(0.27).
132. Petals (16.1)18.3-23.9(25.1) mm long; stigmatic remnants hairy. **26. G. endressii**
132. Petals (13.4)13.8-15.7(17.5) mm long; stigmatic remnants glabrous. **79. G. rectum**
127. Petals apices rounded.
133. Rootstock horizontal or vertical, long, with thickened roots along it or with thin roots.
134. Pedicels with patent, glandular hairs 1.3-3 mm long. **90. G. swatense**
134. Pedicels without glandular hairs.
135. Petals (10.1)11.7-13.4(15.7) mm, hairy on 1/3-1/2 of the adaxial surface. **86. G. rosthornii**
135. Petals (12.9)15.9-18.7(20.6) mm, with hairs only at base.
136. Nectaries with a tuft of hairs at the top, dorsally glabrous; anthers blue black; fruits reflexed when immature. **46. G. yunnanense**
136. Nectaries glabrous; anthers blue or cream; fruits erect. **54. G. palustre**
133. Rootstock vertical, short, with a fascicle of long and thickened roots.
137. Leaves deeply divided [ratio main-sinus length/middle segment length = (0.82)0.86-0.96].
138. Petals (13.4)14.2-18(20) mm long. **59. G. soboliferum**
138. Petals (7.9)9-13(14.6) mm long.

139. Stigmatic remnants (4.5)5.6-6.2(6.6) mm long; nectaries apically with a tuft of hairs; sepals (6.2)7.4-9.1(10) mm long; leaves with the middle segment (4.3)5.4-8.5(8.8) mm wide at base. **58. G. krameri**
139. Stigmatic remnants 2.8-4.5 mm long; nectaries usually glabrous; sepals (5.4)5.8-7.1(9) mm long; leaves with the middle segment (1.6)2.9-4.8(5.7) mm wide at base. **57. G. dahuricum**
137. Leaves moderately divided [ratio main-sinus length/middle segment length = (0.59)0.70-0.81(0.84)].
140. Sepals (5.6)6.6-7.8(8) mm long; petals (9.1)11.4-14.1(15.2) mm long; leaves with the lateral lobes of the middle segment shallowly divided [ratio secondary sinus length/middle segment length = (0.11)0.15-0.18(0.25)]; nectaries glabrous. **53. G. maximowiczii**
140. Sepals (7.9)8.9-10.3(11.2) mm long; petals (15.5)16.1-19.5(23) mm long; leaves with the lateral lobes of the middle segment more divided [ratio secondary sinus length/middle segment length = (0.14)0.21-0.26(0.29)]; nectaries apically with a tuft of hairs. **56. G. wlassovianum**
77. Stipules (2)3-5(11)-fid, with linear to lanceolate and deep lobes. **244. G. ornithopodioides**
141. Leaves peltate.
141. Leaves not peltate.
142. Leaves palmatisect, with lobes narrow (0.3)0.5-2(3.4) mm wide, usually linear. **235. G. vagans**
143. Leaves hairy mainly on the nerves of the abaxial surface, not sericeous.
143. Leaves sericeous on the abaxial surface (but see comments under *G. multisectum*).
144. Leaves with the lateral lobes of the middle segment pinnate,  $\pm$  perpendicular to the plane formed by the segments, which gives the leaf a much entangled appearance when it dries; sepals mucro (0.2)0.4-0.6(0.9) mm long. **234. G. multisectum**
144. Leaves with the lateral lobes of the middle segment entire, lobed or pinnate, all in the same plane; sepals mucro (0.4)0.7-1.3(1.6) mm long. **233. G. incanum**
142. Leaves palmatifid or palmatisect but with wider and not linear lobes.
145. Leaves sericeous on the abaxial surface. **238. G. robustum**
146. Leaves palmatisect.
146. Leaves palmatifid or deeply palmatifid.
147. Leaves densely covered with greyish-white, eglandular hairs or sericeous on the adaxial surface. **240. G. harveyi**
148. Pedicels with only eglandular hairs; sepals (5.1)5.3-6(6.4) mm long.
148. Pedicels with glandular and eglandular hairs; sepals (6.5)6.9-7.6(10) mm long. **241. G. canescens**
147. Leaves with  $\pm$  appressed, eglandular hairs on the adaxial surface.
149. Leaves slightly divided [ratio main-sinus length/middle segment length = (0.54)0.62-0.68(0.76)]. **239. G. discolor**
149. Leaves moderately divided [ratio main-sinus length/middle segment length = (0.73)0.82-0.94(0.97)].

150. Shrubby.  
 151. Petioles with retrorse, appressed hairs; sericeous indumentum of the abaxial surface of the leaves covering the nerves. **236. *G. pulchrum***  
 151. Petioles with patent to retrorse, not appressed hairs; leaves abaxially covered by closely matted-white, eglandular hairs between the nerves and long coarse spreading eglandular hairs over the veins. **237. *G. brycei***
150. Perennial herbs.  
 152. Petals (6.7)8.1-11.9(12.8) mm wide; sepals (6.1)7.3-7.9(8.8) mm long, with glandular hairs 0.3-0.9 mm long. **242. *G. drakensbergense***  
 152. Petals 4.6-6.4 mm wide; sepals 6-6.5 mm long, with glandular hairs 0.6-1.5 mm long. **243. *G. angustipetalum***
145. Leaves  $\pm$  hairy but not sericeous on the abaxial surface.  
 153. Petals narrow [(2.4)3.7-4.3(5) wide] and deeply emarginate. **251. *G. wakkerstroomianum***  
 153. Petals (2.8)4-11(16.6) mm wide, rounded or  $\pm$  emarginate. **246. *G. amatolicum***  
 154. Sepals mucro (1.7)2.4-3.2(3.6) mm long. **247. *G. grandistipulatum***  
 154. Sepals mucro (0.3)0.8-1.4(1.9) mm long. **245. *G. baurianum***  
 155. Stipules 2-3-fid, with lanceolate lobes 1.4-2.2 mm wide. **249. *G. contortum***  
 155. Stipules (2)3-6-fid, with linear lobes 0.2-0.8(1.3) mm wide. **248. *G. schlechteri***  
 156. Leaves slightly divided [ratio main-sinus length/middle segment length = (0.28)0.32-0.43(0.47)]. **250. *G. ornithopodon***  
 156. Leaves moderately divided [ratio main-sinus length/middle segment length = (0.71)0.74-0.83(0.99)]. **252. *G. caffrum***  
 157. Leaves hairy all over of the abaxial surface, moderately divided [ratio main-sinus length/middle segment length = (0.71)0.74-0.83(0.86)]. **253. *G. subglabrum***  
 158. Sepals (7.3)7.6-8.4(8.7) mm long; petals (12.6)13.2-15.8(18.2) mm long. **254. *G. sparsiflorum***  
 158. Sepals (4.5)5.5-6.2(7.7) mm long; petals 6.6-15.3 mm long.  
 159. Leaves with glandular and eglandular hairs on the abaxial surface.  
 159. Leaves with only eglandular hairs on the abaxial surface.
157. Leaves hairy mainly on the nerves of the abaxial surface, deeply palmatifid to palmatisect [ratio main-sinus length/middle segment length = (0.80)0.82-0.98(0.99)].  
 160. Leaves with the middle segment (0.5)0.9-2(3.5) mm wide at the base, deeply palmatifid to palmatisect [ratio main-sinus length/middle segment length = (0.90)0.94-0.98(0.99)].  
 160. Leaves with the middle segment (2.1)3-8.1 mm wide at the base, deeply palmatifid [ratio main-sinus length/middle segment length = (0.80)0.82-0.95(0.96)].  
 161. Petioles with with retrorse, appressed, eglandular hairs 0.3-0.5 mm long; peduncles with glandular hairs 0.1-0.6 mm long.  
 161. Petioles with patent, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.6-1.3 mm long; peduncles with glandular hairs 0.6-1.6 mm long.

**I. *Geranium* subg. *Erodioidea* (Picard) Yeo, Bot. J. Linn. Soc. 89: 10. 1984. TYPE: *G. reflexum* L. (designated by Yeo 1984: 10).**

*Fruit* of *Erodium*-type discharge. At dispersal, mericarp propelled with enclosed seed and attached awn.

**Ia. *Geranium* sect. *Erodioidea* Picard, Mém. Soc. Agric. Boulogne-sur-Mer 2(1): 114. 1837, ["*Erodioideae*"]. TYPE: *G. reflexum* L. (designated by Yeo 1984).**

*Geranium phaeum* f. *linnaei* C.E. Lundstr., Acta Horti Berg. 5: 76, Taf. 4 Fig. 3. 1914. TYPE LOCALITY: [not indicated]. TYPE: cultivated

at Bergius Botanic Garden, C.E. Lundström s.n. (no original material located, S?).

**Perennial herbs**, 25-80 cm tall. **Rootstock** 8-10 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 1.5-2.4 mm long, patent, eglandular hairs 0.1-0.2 mm and patent, glandular hairs 0.1-0.2 mm long. **Basal leaves** in a persistent rosette, cauline leaves alternate; leaf laminae 4-10 cm long, 5.5-11 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.8], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5-7, in 1 plane, middle segment rhombic, 8-15 mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.32], 7-15(26)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.25]; petioles up to 25 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 1.5-2 mm long, patent, eglandular hairs 0.1-0.2 mm long and patent, glandular hairs 0.1-0.2 mm long; stipules 6-8(18) mm long, 2-3(7) mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1-2.1]; peduncles 30-65(100) mm long, with eglandular, patent, hairs 1.5-2 mm long, patent, eglandular hairs 0.1-0.2 mm long and patent, glandular hairs 0.1-0.2 mm long; bracteoles 3-3.5 mm long, 0.5-0.8 mm wide, lanceolate, whorled; pedicels 20-45 mm long, with eglandular, patent, hairs 1.5-2 mm long, patent, eglandular hairs 0.1-0.2 mm long and patent, glandular hairs 0.05-0.2 mm long. Flowers actinomorphic. **Sepals** 7-7.5 mm long, 2.2-3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.3 mm long [ratio mucro length/sepal length

= 0.05-0.06], with  $\pm$  patent, eglandular hairs 1.5-2 mm long and patent, glandular hairs 0.1-0.2 mm long on the abaxial surface, usually glabrous adaxially. **Petals** 8-9(12) mm long, 6-8(9) mm wide, patent to subreflexed, mucronate to rounded, without claw, blackish purple (sometimes with a white spot), hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.2-0.4 mm long. **Stamens** 10, both whorls bearing anthers; filaments 9-10 mm long, lanceolate, purple, glabrous on both surfaces, ciliate on the proximal half, with hairs 1-1.8 mm long; anthers 2.1-2.9 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. **Gynoecium** 10-11 mm long, yellow. **Fruit** 22-25 mm long, erect, discharge of *Erodium*-type; mericarps 5-6 mm long, 1.5-1.8 mm wide, without a strand of fibers, compressed at the apex, with 3-4 transverse ribs at apex, with basal beak 0.2-0.3 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-1 mm long; rostrum 13-15 mm long, with a narrowed apex 2-3 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 1.2-3 mm long, with 5 glabrous lobes. **Seeds** 3-3.2 mm long, 1.5-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 36, 37.

**Pollen.** *Geranium*-type (Bortenschlager 1967: 455; Stafford & Blackmore 1991: 69; Velasco 1992b: 61).

**Chromosome number.**  $2n = 14?, 28$ .

**Phenology.** Collected in flower from May to September.

**Distribution.** This species ranges from western and central to southern Europe (Fig. 38).

**Habitat.** Grassy slopes, roadsides, rocky places and *Alnus* Mill. or *Fagus* L. forests; 50-2200 m.

**Representative specimens examined.**

**Austria.** CARINTHIA: ad margines silvarum pr. Pörschach, 46°37'N, 14°5'E, 22 Aug. 1899, *Jabornegg* s.n. (E, G, LD). LOWER AUSTRIA: Thayatal, Hardegg, 48°50'N, 15°53'E, 10 June 1978, *Grünweis* 267 (MA).

Petal. j. Stamen of outer whorl. k. Staminal filament of inner whorl. l. Mericarp. m. Seed. (Based on: *Aedo & al.* 2401, MA).

**Discussion.** *Geranium phaeum* is easily distinguished from *G. reflexum* and *G. aristatum* because the former has  $\pm$  patent, darker and as long as wide petals, not very narrow and reflexed petals as the latter. A number of minor morphological variants have been recognized, as is evident from the long list of synonyms for *G. phaeum*. After examining ca. 600 sheets I was not able to discern any consistent patterns of variation. The most distinctive differences have been attributed to *G. phaeum* subsp. *lividum*. According to Hess & al. (1977: 628) this taxon differs from typical representatives of *G. phaeum* by its light petals and narrowly lanceolate

Fig. 37. *Geranium phaeum* (Based on: a, Quintanar & al. 1358, MA; b, c, Calvo 4699, MA, photo: J. Calvo; d, Calvo 4799, MA, photo: J. Calvo).

Fig. 38. Distribution of *Geranium phaeum*.

staminal filaments; however, I found many individuals with dark petals and narrowly lanceolate staminal filaments. Furthermore, I did not find any correlation between light petals and other character states, such as color of stigmas and staminal filaments, and thus do not believe “subsp. *lividum*” should formally be recognized. Tschernack-Woess & al. (1954: 97) and Nagl (1962: 448), studying somatic polyploidization and endomitosis, reported  $2n = 14$  for this species, but according to Yeo (1984: 25) this number needs to be confirmed.

It is difficult to determine the exact distribution of this species, which is probably native to the mountains of central and southern Europe (Pyrenees, Alps, Carpathians, etc.) but through cultivations as an ornamental and as fodder has spread northward. According to J. Suominen (*in litt.*) *G. phaeum* cannot be native to Den-

mark, Sweden, and Finland (where it reaches 63°N in Vaasa). The same was suggested by Pawłowska (1959: 337) for the localities in Poland, by Gams (1924: 1691) for localities in Germany, by Clapham & al. (1989: 172) and Stace (1991: 571) for Irish and British records, and by Bonnier (1913: 83) for localities in north-eastern France and Belgium. I was not able to see any Ukraine and Moldavia material, but Bobrov's (1949: 39) report is quite reliable, as well as that from Belorussia by Blazhevich & Shablunskii (1977). On the contrary, according to Persson (1987: 549), Zaganiaris's (1938) report from Belles, Greece, has yet to be confirmed. Its presence in New Zealand, probably as garden-escape, is based on a specimen at CHR could not be studied. Tsyrenova (2006a: 98) recorded *G. phaeum* in Sakhalin (eastern Siberia), as collected in a park (Mazurenko & Khokhryakov s.n., MHA).

*Perennial herbs*, 40-70 cm tall. *Rootstock* 10-16 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 1-2(4.5) mm long and patent, glandular hairs 0.1-0.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves alternate; leaf laminae 5-10.5 cm long, 5-14 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.70-0.80], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5-7, in 1 plane, middle segment rhombic,

8-15 mm wide at the base [ratio segment width at the base/middle segment length = 0.18-0.19], 10-17-lobed in distal half [ratio secondary sinus length/middle segment length = 0.05-0.15]; petioles up to 25 cm long, without abscission zone, terete, not

swollen, not deflexed in age, with patent, eglandular hairs 1.5-2 mm long and patent, glandular hairs 0.1-0.2 mm long; stipules 10-14(16) mm long, 3-3.5(7) mm wide, lanceolate, free, papery, brown, with glandular or eglandular hairs on abaxial surface

and on the margin, usually glabrous adaxially. *Inflorescence* a monochaetial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.8-2.2]; peduncles 15-85 mm long, with patent, eglandular hairs 1-2 mm long and patent, glandular hairs 0.1-0.2 mm long; bracteoles 3-6 mm long, 0.4-0.5 mm wide, lanceolate, whorled; pedicels 23-30 mm long, with patent, eglandular hairs 1-2 mm long and patent, glandular hairs 0.1-0.2 mm long. Flowers actinomorphic. *Sepals* 7-10 mm long, 3-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.5 mm long [ratio mucro length/sepal length = 0.10-0.11], with  $\pm$  patent, eglandular hairs 2-3 mm long and patent, glandular hairs 0.1-0.2 mm long on the abaxial surface, glabrous adaxially. *Petals* 9-12 mm long, 3.5-6.5 mm wide, reflexed, rounded to erose, without claw, deep purple with a white base, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.6-1.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 8-9 mm long, lanceolate, white with purple apex, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-0.8 mm long; anthers 2.2-2.5 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 10-11 mm long, yellow. *Fruit* 27-31 mm long, reflexed when immature, discharge of *Erodium*-type; mericarps 4.5-5 mm long, 1.5-1.7 mm wide, without a strand of fibers, compressed at the apex, with 2-3 transverse ribs at apex, with basal beak 0.3-0.4 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-1 mm long; rostrum 20-21 mm long, with a narrowed apex 1.5-3 mm long, not twisted, with erect-patent, eglandular hairs 0.1-1 mm long; stigmatic remnants 1.5-2 mm long, with 5 glabrous lobes. *Seeds* 3.2-3.5 mm long, 1.5-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 39, 40.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 429).

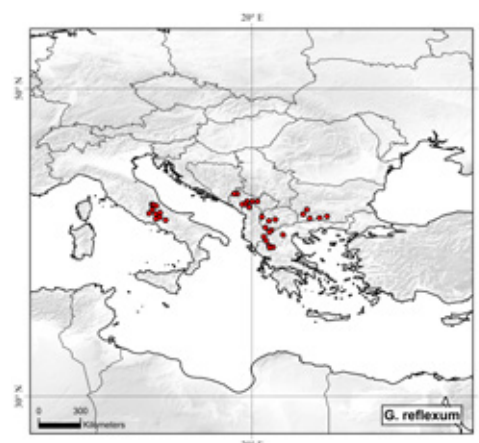

Fig. 41. Distribution of *Geranium reflexum*.

*Discussion.* *Geranium reflexum* is probably closest to *G. phaeum*. Both species have alternate lower cauline leaves and simple or bifurcate monopodial branching, but they differ in the position and size of petals, and in other floral and fruiting characters.

Knuth (1912: 577) listed *G. tuberosum* f. *hirta* Formánek as synonym for *G. reflexum*. I was not able to find any sheet that could be linked to the protologue of Formánek's name at BRNM. Because Formánek's diagnosis is very short and only slightly informative, *G. tuberosum* f. *hirta* should be considered as a doubtful synonym of *G. reflexum*.

**3. *Geranium aristatum*** Freyn & Sint., Bull. Herb. Boissier 5: 587. 1897. TYPE LOCALITY: "Thessalia graeca in fissuris rupium montis Plaka Pindi tymphaei prope pagum Chaliki rarum die 4. Julii 1896 leg. Sintenis (exs. 673)". TYPE: Greece. Chaliki, mont Plaka, Thessalia graeca, 39°40'N, 21°08'E, 4 July 1896, *P. Sintenis* 673 (lectotype, designated by Aedo 1996: 83, LD-1035606; isoelectotypes, BRNM-10586 image!, PRC-455270 image!).

*Perennial herbs*, 20-70 cm tall. *Rootstock* 6-10 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with  $\pm$  patent, eglandular hairs 0.3-1.5 mm long. *Basal leaves* in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminae 5-7.5 cm long, 5-8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.78-0.80], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular hairs and, sometimes, scattered glandular hairs; segments 5-7, in 1 plane, middle segment rhombic, 8-15 mm wide at the base [ratio segment width at the base/middle segment length = 0.16-0.23], 10-22-lobed in distal half [ratio secondary sinus length/middle segment length = 0.20-0.38]; petioles up to 22 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.8-1 mm long and, sometimes, patent, glandular hairs 0.3-0.9 mm long;

stipules 10-16 mm long, 2-3 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.5-1.6]; peduncles 15-30 mm long, with patent, eglandular hairs 0.5-1.5 mm long and patent, glandular hairs 0.1-0.2 mm long; bracteoles 7-9 mm long, 0.5-0.6 mm wide, lanceolate, whorled; pedicels 16-28 mm long, with patent, eglandular hairs 0.6-1.5 mm long and patent, glandular hairs 0.1-0.2 mm long. Flowers actinomorphic. *Sepals* 8-10 mm long, 3-4 mm wide, lanceolate, smooth, not accrescent, nerves 3(5), mucro 4-5(7) mm long [ratio mucro length/sepal length = 0.40-0.47], with  $\pm$  patent, eglandular hairs 2-3.5 mm long and patent, glandular hairs 0.1-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* 11-12 mm long, 5-5.5 mm wide, reflexed, mucronate (sometimes rounded), without claw, strong purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.7-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7-9 mm long, lanceolate, light purple, glabrous on both surfaces, ciliate on the proximal half, with hairs 0.2-0.9 mm long; anthers 2.5-2.9 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6-7 mm long, yellow. *Fruit* 35-39 mm long, erect, discharge of *Erodium*-type; mericarps 7-8.5 mm long, 2-2.1 mm wide, without a strand of fibers, compressed at the apex, with 2-3 transverse ribs at apex, with basal beak 1-1.5 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-1 mm long; rostrum 28-30 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 1.5-1.7 mm long, with 5 glabrous lobes. *Seeds* 4.5-4.7 mm long, 1.8-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with a notch on each side margin. Fig. 42.

*Pollen*. Ornamentation not studied. *Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from June to August.

*Distribution*. This species ranges from Albania, western Bulgaria and North Macedonia to northwestern Greece (Fig. 43).

*Habitat*. Shady, damp places in clearings of *Fagus* L. forests or alpine meadows, also in rock crevices, on limestone or igneous rocks; 1000-2200 m.

*Additional specimens examined*. **Albania**. DIBËR: Bulqizë, villaggio di Qyteti, presso Bulqizë, 41°31'N, 20°13'E, 13 June 2017, *Cecchi s.n.* (FI). **Bulgaria**. **Discussion.** *Geranium aristatum* is easily recognized by its reflexed petals, the long mucro of the sepals, and the opposite cauline leaves. Knuth (1912: 133) suggested that *G. aristatum* should be included in *G. reflexum*, because both *Sintenis* 673 (the type of *G. aristatum*) and *Sintenis* 675 (which is *G. reflexum*) came from the same locality, but he had not examined any material of *G. aristatum*. In most individuals glandular hairs are usually confined to the inflorescence, but some plants have glandular hairs on the leaves and the lower part of the stem as well. I found both types of plants in a large set kept at G (G-188590). López (1982: 528) found the same variation even in only one plant of *Geranium collinum*. Thus, like Persson (1987: 544), I do not accord taxonomic recognition to this variation. In any case, the type material I examined has several glandular hairs only in the inflorescence and the upper part of the stem.

**Ib. *Geranium* sect. *Aculeolata*** Yeo in P. Vorster, Proc. Intern. Geraniaceae Symp.: 22. 1990. TYPE: *G. aculeolatum* Oliv. (art. 10.8).

*Stem* scandent, leafy, with prickles. *Cymules* 2-flowered. *Petals* erect-patent. *Cotyledons* with two notches on each side.

**Discussion.** *Geranium aculeolatum* is a long, scandent perennial herb sometimes rooting on nodes; the underground parts are unknown. It is always easily identified by the prickles covering younger parts of stems; in older parts the hairs are sloughed off, and the prickles are broken but stumps remain. This feature is a unique condition in the entire genus, but *G. latilobum* shows stout eglandular hairs, some of them prickly-like. *Geranium aculeolatum* has an inflorescence with cymules arranged monochasially, opposite leaves with broadly lanceolate, connate stipules ending in a setaceous apex, short petals and fruit of the *Erodium*-type of discharge. The mericarps has a basal small callus, not so developed as in other groups of *Geranium*. In contrast with other species of the subgenus *Erodioidea* the mericarps ends abruptly, that is without basal beak.

The type of *G. bequaertii* is a fragment with not well-developed fruits

whose identity has been difficult to clarify. It has, however, some peduncles with small prickles that indicate unequivocally that is a specimen of *G. aculeolatum*.

**1c. *Geranium* sect. *Subacaulia*** (Boiss.) Reiche in Engl. & Prantl, Nat. Pflanzensfam. 3(4): 8. 1890. *Geranium* [5] *Subacaulia* Boiss., Fl. Orient. 1: 869. 1867. TYPE: *G. subcaulescens* L'Hér. ex DC. (art. 10.8).

*Geranium* sect. *Petraea* Bubani, Fl. Pyren. 3: 312. 1901. TYPE: *G. varium* L'Hér. [= *G. cinereum* Cav.] (designated by Aedo 1996: 23).

**Stem** scapiform or subscapiform, usually prostrate, without prickles. **Cymules** usually 2-flowered. **Petals** erect-patent. **Cotyledons** with entire margins.

*Geranium varium* L'Hér., Geraniologia, tab. 37. 1792. TYPE LOCALITY: [not indicated]. TYPE: France. Pyrénées, *J.P. Lamouroux s.n.* (lectotype, designated by Aedo 1996: 35, NEU!).

**Perennial herbs**, 7-35 cm tall. **Rootstock** 4-8 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. **Stem** prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, not appressed, eglandular hairs 0.1-0.2 mm long. **Basal leaves** in a persistent rosette, cauline leaves usually absent, sometimes 1-2(3) pairs, opposite; leaf laminae 2.2-3 cm long, 2.6-3.4

cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.70-0.85], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 3-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.21-0.27], 3(7)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.13-0.33]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, not appressed, eglandular hairs 0.1-0.2 mm long; stipules 10-11 mm long, 2-2.5 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. **Cymules** 2-flowered, solitary [ratio cymule length/leaf length = 1.3-1.5]; peduncles 50-150 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.2 mm long; bracteoles 7-10 mm long, 1-1.3 mm wide, linear-lanceolate, whorled; pedicels 20-50 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.2 mm long. Flowers actinomorphic. **Sepals** 8-10 mm long, 3-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 1-1.7 mm long [ratio mucro length/sepal length = 0.11-0.19], with eglandular hairs 0.1-0.5 mm long on the abaxial surface (0.5-0.7 mm long on the margin), glabrous adaxially. **Petals** 14-17 mm long, 11-12 mm wide, erect-patent, emarginate (notch 0.8-1.5 mm deep), without claw, purple (without a dark basal spot), hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.9 mm long. **Stamens** 10, both whorls bearing anthers; filaments 5.5-6.5 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal third, with hairs 0.1-0.3 mm long; anthers 1.8-2.2 mm long, deep purple. Nectaries 5, hemispheric, glabrous. **Gynoeceum** 8-9 mm long, yellow. **Fruit** 32-33 mm long, erect, discharge of *Erodium*-type; mericarps 6-6.2 mm long, 2-2.5 mm wide, without a strand

of fibers, compressed at the apex, with 2 transverse ribs at apex, with basal beak 0.8-0.9 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-0.9 mm long; rostrum 21-24 mm long, without a narrowed apex, not twisted,

with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 2.3-3 mm long, with 5 hairy lobes. *Seeds* 3.5-4 mm long, 1.5-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 47, 48.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 425, Velasco 1992b: 62).

*Chromosome number.*  $2n = 28$ .

*Phenology.* Collected in flower from June to August.

*Distribution.* This species ranges from eastern Cantabrian Mountains to central Pyrenees (Fig. 49).

*Habitat.* Grassy slopes and ledges of limestone or igneous rocks; 1200-2650 m.

Fig. 47. *Geranium cinereum*. a. Habit. b. Leaf. c. Portion of peduncle and detail showing indumentum. d. Sepal and detail showing indumentum. e. Petal. f. Staminal filament of outer whorl. g. Staminal filament of inner whorl. h. Mericarp. (Based on: Montserrat s.n., MA-331309).

*Discussion.* *Geranium cinereum* is probably related to *G. cazorlense*; the two species grow allopatrically in the Iberian Peninsula. They differ in details of the indumentum of the leaves, peduncles, and pedicels, and the morphology of the staminal filaments. *Geranium cinereum* is a somewhat variable species. In some herbarium material (e.g., *Morales 499*, *Morante & Alejandro 1488/89*, *Uribe & Urrutia s.n.* MA-478857) I found some unusual leaves with 5-7-lobed segments; however, most of the leaves are always 3-lobed.

**6. *Geranium subargenteum*** Lange in Willk. & Lange, Prodr. Fl. Hispan. 3: 525. 1878. *Geranium cinereum* subsp. *subargenteum* (Lange) Borja ex M. Lainz, Supl. Ci. Bol. Inst. Estud. Fig. 51. *Geranium subargenteum* (Based on: Aedo 15852, MA).

Fig. 52. Distribution of *Geranium subargenteum*.

**Discussion.** *Geranium subargenteum* is probably closely related to *G. dolomiticum*. Both Cantabrian species have mericarps without a basal callus (like *G. cazorlense*) and leaves more deeply divided than those of other species of the western Mediterranean region. The deep purple staminal filaments, sepals without long marginal hairs, and discolorous leaves (pilose above and sericeous beneath) are three useful characters that distinguish *G. subargenteum*.

TYPE: Spain. León, La Guiana, Los Apóstoles, 42°30'N, 6°36'W, 15 June 1933, W. Rothmaler 49 (lectotype, designated by Velasco 1992a: 296, ZI; isoelectotypes, BC-80054!, BM, JE-00019621!, MA-71421!, MAF-25277!).

*Perennial herbs*, (6)9-25(40) cm tall. *Rootstock* 5-9 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.1-0.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1(3) pairs, opposite; leaf laminae (3)5-6 cm long, (4)5-7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.73-0.77], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment obtriangular, 4-7 mm wide at the base [ratio segment width at the base/

middle segment length = 0.21-0.29], (3)5-8-lobed in distal half [ratio secondary sinus length/middle segment length = 0.16-0.38]; petioles up to 28 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; stipules 9-13 mm long, 2-2.5 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Cymules* 2-flowered, solitary [ratio cymule length/leaf length = 1.1-6.2]; peduncles (30)60-140 mm long, with patent, eglandular hairs 0.1-0.2 mm long; bracteoles 5-6 mm long, 0.5-0.7 mm wide, linear-lanceolate, whorled; pedicels 25-50 mm long, with patent, eglandular hairs 0.1-1 mm long. Flowers actinomorphic. *Sepals* 6.5-8.2 mm long, 2.6-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 1-2.5 mm long [ratio mucro length/sepal length = 0.12-0.16], with patent, eglandular hairs 0.1-0.2 mm long on the abaxial surface (1.5-2 mm long on the margin), glabrous adaxially. *Petals* 12-13 mm long, 6.4-8.5 mm wide, erect-patent, emarginate (notch 0.9-1.1 mm deep), without claw, purple (without a dark basal spot), hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.5-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5-6 mm long, lanceolate, yellow, pilose on the abaxial

surface, ciliate on the proximal half, with hairs 0.3-0.5 mm long; anthers 2-2.2 mm long, deep purple. Nectararies 5, hemispheric, glabrous. *Gynoe-cium* 7-8 mm long, yellow. *Fruit* 24-28 mm long, erect, discharge of *Erodium*-type; mericarps 5.6-6 mm long, 2-2.2 mm wide, without a strand of fibers, compressed at the apex, with 2 transverse ribs at apex, with basal beak 0.7-0.8 mm long, without a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-1 mm long; rostrum 17.2-20 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 1.2-2.5 mm long, with 5 hairy lobes. *Seeds* 3-3.6 mm long, 1.6-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 53, 54.

*Pollen.* *Geranium*-type (Velasco 1992b: 63).

*Chromosome number.*  $2n = 28$ .

*Phenology.* Collected in flower from June to August.

*Distribution.* This species is endemic to northwestern Spain (Fig. 55).

*Habitat.* Crevices and on ledges of dolomite rocks, also close to rocks on substrates nitrogen-enriched by animal feces; 850-1650 m.

*Additional specimens examined. Spain.*

*Discussion.* *Geranium dolomiticum* is found only in a small area in the south-east of the Cantabrian Mountains. It has more deeply divided leaves than

Fig. 53. *Geranium dolomiticum*. a. Habit. b. Leaf. c. Detail showing indumentum of leaf surface. d. Portion of peduncle. e. Detail showing indumentum of peduncle. f. Sepal. g. Detail showing indumentum of sepal. h. Petal. i. Stamen of outer whorl. j. Stamen of inner whorl. k. Mericarp. l. Seed. (Based on: *Aedo* 2433, MA).

Fig. 54. *Geranium dolomiticum* (Based on: Aedo 22987, MA).

other species of sect. *Subacaulia*; only one other Cantabrian taxon (*G. subargenteum*) and two Caucasian ones (*G. lazicum* and *G. ponticum*) have similar leaves. *Geranium dolomiticum* is also close to *G. subargenteum* in other features, such as the absence of the basal callus of the mericarp. The color of the staminal filaments and the indumentum of leaves and sepals separate the two species. As a historic consideration, it is worth noting that Pierre André Pourret (1754-1818) had collected this plant at the beginning of the 19th century near the place where *G. dolomiticum* was found by Rothmaler more than 100 years later. Unfortunately, Pourret never published his discoveries of new species in the northwestern Spain.

**8. *Geranium cazorlense*** Heywood, Bull. Brit. Mus. (Nat. Hist.), Bot. 1: 112. 1954. *Geranium cinereum* subsp. *cazorlense* (Heywood) Fern. Casas, Trab. Dep. Bot. Univ. Granada 1: 37. 1972. TYPE LOCALITY: "Prov. Jaén: Montes de Cazorla, Sierra de Pozo Alcón, Pico de

Cabañas, near and under limestone arch, in limestone crevices, rocks, flowers white veined with violet, 1 July 1948, Heywood & Davis 447 (BM, holotype; C; E; K)". TYPE: Spain. Jaén, Montes de Cazorla, Sierra de Pozo Alcón, Pico de Cabañas, 37°48'N 2°56'W, 1 July 1948, V.H. Heywood & P.H. Davis 447 (holotype, BM-000751350!; isotypes, C, E, K; according to Velasco 1992a, erroneously, also at MA).

*Perennial herbs*, 1-9 cm tall. *Root-stock* 5-8 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, appressed, eglandular hairs 0.1-0.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1(2) pairs, opposite; leaf laminae 1.1-2.2 cm long, 1.4-2.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.60-0.82], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both

Fig. 58. Distribution of *Geranium cazorlense*.

**Habitat.** Crevices of limestone rocks; 1800-2050 m.

**Additional specimens examined. Spain.** JAÉN: pico Cabañas, 37°48'N, 2°56'W, 20 July 1977, *Castroviejo & Valdés Bermejo 2579EV* (MA); Sierra Cazorla, pico de Cabañas, 37°48'N, 2°56'W, 23 July 1973, *Fernández Casas s.n.* (MA); Sierra de Cazorla, pico de Cabanos, 37°48'N, 2°56'W, 14 Sep. 1960, *Gibbs 205* (BM); Pozo Alcón, pico de Cabañas, 37°48'N, 2°56'W, 27 Sep. 1975, *González Rebollar & al. s.n.* (MA); Pozo Alcón, pico Cabañas, 37°48'N, 2°56'W, 20 June 1975, *González Rebollar & al. s.n.* (MA); Sierra Cazorla, pico de Cabañas, 37°48'N, 2°56'W, 24 July 1971, *Morales & Fernández Casas s.n.* (MA); Quesada, W del barranco de los Tornillos, pr. puerto Llano, 37°49'N, 2°56'W, 7 July 1976, *Muñoz Garmendia & Soriano 3163* (MA); Sierra Cazorla, pico de Cabañas, 37°48'N, 2°56'W, 6 Aug. 1968, *Segura Zubizarreta s.n.* (MA); Pozo Alcón, pico de Cabañas, 37°48'N, 2°56'W, 18 July 1980, *Soriano 1177* (MA); Pozo Alcón, pico de Cabañas, 37°48'N, 2°56'W, 27 Sep. 1979, *Soriano s.n.* (MA).

**Discussion.** *Geranium cazorlense* is found only in a small area in the southeast of Spain. It is probably related to *G. nanum*. Both have white or pale-pink petals (like *G. makmelicum*) and short leaves. The indumentum of the sepals and especially the auriculate staminal filaments serve to separate *G. cazorlense* from *G. nanum*.

**Discussion.** *Geranium nanum* has very small leaves and quite often has the pedicels arising from the root-stock. These characteristics seem to be constant in populations at upper elevations, even in shaded habitats (3200 m, *Balls* 307J, BM!). At lower altitudes (2800 m, *Dovignard* 3832, G-301700!) *G. nanum* has considerably larger leaves, but other qual-

itative characters of indumentum, leaves, and flowers are the same. Quézel (1957: 393) proposed  $n = 13$  as the chromosome number for this species; however, Guittonneau (1975: 200), after studying plants from Quézel's locality (Ayachi), stated that  $n = 13$  might be an incorrect number for *G. nanum*. Favarger & al. (1979: 34-35, 52) came to the same conclusion and proposed  $2n = 28$  as the only number for this species.

**10. *Geranium argenteum* L., Cent. Pl. II: 25. 1756.** TYPE LOCALITY: "Habitat in Baldi summis praeruptis rupibus Seguier". TYPE: Italy. "Habitat in Baldi summis praeruptis rupibus", 45°43'N, 10°50'E, *J.F. Séguier s.n.* (lectotype, designated by Aedo 1996: 39, LINN-858.67 image!).

*Perennial herbs*, 5-21 cm tall. *Rootstock* 6-8 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, not appressed, eglandular hairs 0.2-0.4 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1(2) pairs, opposite; leaf laminas 1-1.8(4) cm long, 2.5-2.8(4) cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, sericeous on both surfaces, with appressed, eglandular hairs; segments 5(7), in more than 1 plane, middle segment obtriangular, 1-2 mm wide at the base [ratio segment width at the base/middle segment length = 0.06-0.09], 3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.35-0.59]; petioles up to 9 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.3 mm long; stipules 12-14 mm long, 2.2-2.5 mm wide, lanceolate, free, papery, brown, with

eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Cymules* 2-flowered, solitary [ratio cymule length/leaf length = 1.2-1.8]; peduncles 20-80(150) mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; bracteoles 6-8 mm long, 1-1.5 mm wide, linear-lanceolate, whorled; pedicels 20-50 mm long, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long. Flowers actinomorphic. *Sepals* 7-9 mm long, 3-4.5 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 0.5-1.5 mm long [ratio mucro length/sepal length = 0.11-0.13], sericeous, with eglandular hairs 0.2-0.4 mm long on the abaxial surface (without long hairs on the margin), glabrous adaxially. *Petals* 14-15 mm long, 11-13 mm wide, erect-patent, emarginate (notch 0.5-1 mm deep), without claw, pink (without a dark basal spot), hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.5-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7-8 mm long, lanceolate with an abruptly narrowed apex, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.4 mm long; anthers 2.2-2.5 mm long, yellow with purplish lines. Nectaries 5, hemispheric, glabrous. *Gynoeceium* 7-8 mm long, yellow. *Fruit* 25-27 mm long, erect, discharge of *Erodium*-type; mericarps 5.5-6.8 mm long, 2-2.2 mm wide, without a strand of fibers, compressed at the apex, with 1-2 transverse ribs at apex, with basal beak 0.7-1 mm long, with a basal callus, without a basal prong, brown, with appressed, eglandular hairs 0.5-2 mm long; rostrum 18-19 mm long, without a narrowed apex, not twisted, with appressed, eglandular hairs 0.2-0.3 mm long; stigmatic remnants 1.9-2.7 mm long, with 5 hairy lobes. *Seeds* 3.5-3.6 mm long, 1.9-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 62, 63.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 427).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from June to September.

*Distribution*. This species ranges from southeastern France, through northern and central Italy to Slovenia (Fig. 64).

*Habitat*. Grassy slopes and ledges of limestone, dolomite, or igneous rocks; 1300-2700 m.

*Representative specimens examined*. **Italy**. EMILIA-ROMAGNA: mont Cimone, da Pian Cavallaro alla vetta Prati rocciosi, 44°12'N, 10°42'E, 12 Aug. 1988, *Foggi s.n.* (BM, FI). *Discussion*. *Geranium argenteum* is a very distinctive species always easily identified by its sericeous palmatisect leaves with very deeply 3-lobed segments. It is unlikely to be confused with any other species. It has been reported from three isolated areas: a) southern French Alps; b) northwest of

Fig. 62. *Geranium argenteum*. a. Habit. b. Leaf. c. Detail showing indumentum of leaf surface. d. Portion of peduncle. e. Sepal. f. Detail showing indumentum of sepal. g. Petal. h. Fig. 63. *Geranium argenteum* (Based on: *Aedo* 20891, MA).

the Apennines; c) Slovenian Alps and northeastern Italy. Octaviano's locality (Bertoloni 1850: 225), which would be the southernmost for the species, "ex Umbria in montibus delle Fonti prope il Sasso Borghese" (42°50'N, 13°18'E), has been reported by many authors (Chiarugi 1937: 639; Favarger 1975: 39; Ferrarini 1967: 379; Fiori & Paoletti 1901: 238; Parlato 1873: 137). I did not see any material from the Abruzzo mountains, and I agree with Pignatti (1982: 6) that this locality must be confirmed.

*Geranium argenteum* var. *lucanum* N. Terracc., Nuov. Giorn. Bot. Ital. ser. 2, 14: 137. 1907. TYPE LOCALITY: "Salinice". TYPE: Italy. Basilicata, Salinice, 40°45'N, 15°28'E, *N. Terracciano s.n.* (no original material located, NAP?, Aedo 1996: 39).

*Perennial herbs*, 5-20 cm tall. *Rootstock* 5-12 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with usually patent, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1(2) pairs, opposite; leaf laminae 1.4-2.8 cm long, 1.6-3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.6-0.7], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment obtriangular, 2-5 mm wide at the base [ratio segment width at the base/middle segment length = 0.06-0.09], 3-4(5)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.17-0.41]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.1-0.3 mm long; stipules 5-7 mm long, 0.9-2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 2-flowered, solitary [ratio cymule length/leaf length = 1.2-1.8]; peduncles 40-120 mm long, with patent, eglandular hairs 0.1-0.5 mm long; bracteoles 4-5 mm long, 0.8-1 mm wide, lanceolate, whorled; pedicels

20-55 mm long, with patent, eglandular hairs 0.1-0.5 mm long. Flowers actinomorphic. *Sepals* 8-9 mm long, 2.5-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3(5), mucro 0.7-1.1 mm long [ratio mucro length/sepal length = 0.11-0.13], with eglandular hairs 0.1-0.5 mm long on the abaxial surface (0.7-1 mm long on the margin), glabrous adaxially. *Petals* 14-15 mm long, 9-10 mm wide, erect-patent, emarginate (notch 1-1.1 mm deep), without claw, purple (without a dark basal spot), glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6-7 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal third, with hairs 0.2-0.3 mm long; anthers 2-2.5 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 8-9 mm long, yellow. *Fruit* 32-35 mm long, erect, discharge of *Erodium*-type; mericarps 7-8 mm long, 1.6-2.5 mm wide, without a strand of fibers, compressed at the apex, with 1-2 transverse ribs at apex, with basal beak 1-1.1 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 1-1.2 mm long; rostrum 23-25 mm long, without a narrowed apex, not twisted, with subappressed, eglandular hairs 0.2-0.3 mm long; stigmatic remnants 1.5-2.1 mm long, with 5 usually glabrous lobes. *Seeds* 4.5-5 mm long, 1.5-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 65, 66.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to July.

*Distribution*. This species ranges through central and southern Apennines, in Italy (Fig. 67).

*Habitat*. Grassy or rocky places on limestone; 1500-2000 m.

*Additional specimens examined*. **Italy**. E montibus regno napolitano, *Moricand s.n.* (G). ABRUZZO: L'Aquila, Gole di Sagittario, carretera de Anversa a Villalago, 41°49'N, 13°56'E, 4 July 2002, *Herrero & al.* 2073

*Discussion*. Specimens of sect. *Subacaulia* from the central and southern Apennines here assigned to *G. austroapenninum* traditionally have been considered conspecific with the Pyrenean *G. cinereum* (Bertoloni 1850: 225; Fiori & Paoletti 1901: 238; Parlato 1873: 138; Tenore 1820: 101). More recently these specimens have been identified as *G. cinereum* subsp. *subcaulescens* (Davis & Roberts 1955: 21; Pignatti 1982: 6). Curiously, Terracciano (1890), in his *Specie rare o critiche di geranii italiani*, did not deal with this difficult group. The plants from the southern and central Apennines that I examined differ from *G. cinereum* by the dense patent hairs on petioles, peduncles and pedicels the deep purple staminal filaments, and the more deeply divided leaves with 3-5 lobes per segment. *Geranium cinereum* has sparse, retrorse, appressed hairs (especially on petioles, peduncles, and pedicels), yellow staminal filaments, and less deeply divided leaves with

usually 3-5-lobes per segment. In addition, plants of *G. austroapenninum* can also be distinguished from *G. subcaulescens* by the petals, which lack a dark basal spot, the color of the staminal filaments and stigmas, and the more deeply divided leaves. *Ge-*

*ranium subcaulescens* has petals with a dark basal spot, very dark purple staminal filaments and stigmas, and leaves with usually 3 lobes per segment. In view of these differences I recognized the Italian populations as a separate species (Aedo 1994).

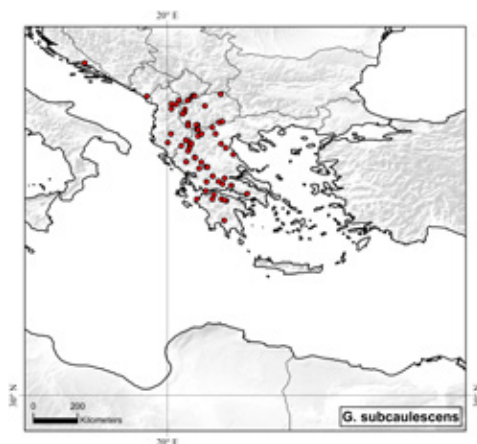

Fig. 70. Distribution of *Geranium subcaulescens*.

**Discussion.** According to some authors this Balkan species grows also in Turkey and Lebanon (Boissier 1867: 872; Mouterde 1966: 435), while others believe that it reaches the Apennines in Italy (see under *G. austroapenninum*). The inclusive circumscription is supported by Da-

vis (1967: 471), who recognizes *G. subcaulescens* as subspecies of *G. cinereum* (and all the Turkish taxa as varieties). However, I maintain that there are two endemic Balkan species: *G. thessalum*, with 1- 2-lobed leaf segments and pale flowers, and *G. subcaulescens*, with more deeply divided leaves and a typical dark spot on the petals. The following describes the most notable variability of *G. subcaulescens*. The orientation of the hairs of the petiole, peduncle, and pedicel has been considered a useful character in other species of sect. *Subacaulia*, but it is too variable a feature in *G. subcaulescens*. As a general rule this species has patent hairs; however, among plants from Mount Ossa and Mount Peristéri

(northern Thessalia, Greece) I have found specimens with both patent and retrorse hairs. Northward, especially in Macedonian localities, retrorse hairs are also common. The sepal hairs are short and appressed on the surface and long and  $\pm$  patent on the margin; however, in some localities (as in northern Macedonia) I found plants with only short and appressed hairs on the surface but none on the margin. Thus, the variation of the indumentum does not fit a geographic pattern and should not be used to segregate any local taxa. The dark basal spot on the petal is usually very large and covers the proximal third. Yet, in some cases it is much smaller and restricted to the very base of the petal (usually in poorly prepared specimens); thus, a light (or white) strip separates the two zones. Persson (1987: 541) may have referred to this when he stated: "In Peloponnisos and Sterea Ellas specimens of *G. subcaulescens* with white-based petals are quite common, and specimens with pink petals can also be found". Furthermore, I have found that very dark purple staminal filaments, anthers, and stigmas are closely correlated with the dark basal spot of the petals. I found two anomalous collections (*Guiol s.n.*, BM; *Heldreich s.n.*, E), from Mount Cithaeron (southeastern Greece), which lack dark pigmentation in the petals, staminal filaments, anthers, and stigmas. I believe that a local loss of pigmentation has become stabilized in peripheral populations of *G. subcaulescens*; obviously, these plants are difficult to separate from *G. subacutum*. *G. subcaulescens* is closely related to *G. austroapenninum* and *G. subacutum*. I did not recognize any of them at the subspecific rank, because they do not intergrade in areas of contact.

Baltisberger (1993: 12) reported  $2n = 56$  in *G. subcaulescens* from northern Macedonia, which is the only tetraploid number reported in subg. *Erodioidea*. I examined the voucher (*Baltisberger & Schappi* 12250,

ZT) and some others collections from the same locality, and found that they do not differ from typical representatives of *G. subcaulescens*.

*Perennial herbs*, 5-19 cm tall. *Rootstock* 10-16 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with usually patent, eglandular hairs 0.2-0.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1-2 pairs, opposite; leaf laminae 1.8-2.8 cm long, 2.1-3.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.80], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose above and sericeous

beneath, with appressed, eglandular hairs; segments 5(7), in 1 plane, middle segment obtriangular, 2-3 mm wide at the base [ratio segment width at the base/middle segment length = 0.26-0.28], (1)2(3)-lobed in distal half [ratio secondary sinus length/middle segment length = 0-0.18]; petioles up to 7(10) cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; stipules 4-6 mm long, 2-2.3 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 2-flowered, solitary [ratio cymule length/leaf length = 1.2-1.3]; peduncles 60-80 mm long, with usually appressed, eglandular hairs 0.2-0.4 mm long; bracteoles 4-5 mm long, 1-1.1 mm wide, linear-lanceolate, whorled; pedicels 40-60(100) mm long, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long. Flowers actinomorphic. *Sepals* 8-9(10) mm long, 2.5-3 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 0.7-1.2 mm long [ratio mucro length/sepal length = 0.13-0.14], sericeous, with appressed, eglandular hairs 0.2-0.4 mm long on the abaxial surface (without long hairs on the margin), glabrous adaxially. *Petals* (12)16-17 mm long, 10-12 mm wide, erect-patent, slightly emarginate (notch 0.5 mm deep), without claw, purple (without a dark purple basal spot), glabrous on the adaxial surface, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.5-6 mm long, lanceolate with an abruptly narrowed apex, yellow, pilose on the abaxial surface, ciliate on the proximal third, with hairs 0.3-0.5 mm long; anthers 2-2.5 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5-6 mm long, yellow. *Fruit* 32-33 mm long, erect, discharge of *Erodium*-type; mericarps 7-7.5 mm long, 2-2.1 mm wide, without a strand of fibers, compressed at the apex, with (0)1 transverse rib at apex, with basal

beak 1 mm long, with a basal callus, without a basal prong, brown, with ± appressed, eglandular hairs 0.7-1 mm long; rostrum 22-24 mm long, without a narrowed apex, not twisted, with ± appressed, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 1.8-2 mm long, with 5 glabrous lobes. *Seeds* 4-4.1 mm long, 1.5-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 71, 72.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to August.

*Distribution*. This species ranges from North Macedonia to northern Greece (Fig. 73).

*Habitat*. Rocky limestone slopes; 1100-2100 m.

*Additional specimens examined*. **Greece.**

WEST MACEDONIA: Kozanis, Mt. Siniatsikon (Askion), 6 km SSE of the village of Vlasti, 40°24'N, 21°33'E, 30 Aug. 1980, Franzén 240 (LD); nom. Kozani, Mt. Siniatsikon, 6 km SSE of the Vlasti, 40°24'N, 21°33'E, 30 Aug. 1980, Franzén s.n. (B); nom. Kozani, eparchia Vojos, Askion (Siniatsikon) Massiv, östlich von Namata, 40°24'N, 21°33'E, 21 Aug. 1983, Hagemann & al. 1246 (B); eparchia Vojos, Askion (Siniatsikon) Massiv, östlich von Namata, 40°24'N, 21°33'E, 22 Aug. 1983, Hagemann & al. 1269 (B); Kozani, Askio, monte Siniatsikon, por encima de Námata, 40°24'N, 21°32'E, 1 July 2007, Herrero & al. 3600 (MA); Kozani, Askio, monte Siniatsikon, por encima de Námata, 40°24'N, 21°32'E, 1 July 2007, Herrero & al. 3648 (MA).

*Discussion*. *Geranium thessalum* was discovered by Micevski (1980: 29), who described it as *G. cinereum* var. *pallidum*. Later, Franzén (1983: 549) proposed the new heterotypic name at the specific level, perhaps because he was unaware of Micevski's paper. This species is easily distinguished from *G. subcaulescens*. Although clearly a member of sect. *Subacaulia*, it does not have an obvious sister-species. I saw only the type of the taxon described as *G. cinereum* var. *liskensis* but no additional collections. It is very similar to *G. thessalum*, particularly in its elliptic 2-lobed leaf segments, but

differs in its very dark purple staminal filaments. I include Micevski's variety in *G. thessalum* with some hesitancy. Persson (1987: 541) refers to a plant perhaps related to *G. thessalum*, collected in Dhouskon (northern Greece, pr. Albania boundary, Hartvig 896). Unfortunately, I was not able to examine any specimen of this collection, since I did not find any duplicates of Hartvig's number at B, C, or G; ATH did not respond to my loan request.

**Discussion.** *Geranium subacutum*, endemic to Turkey, has purplish petals (without a dark basal spot) and leaves with usually 3-lobed segments. It differs from *G. subcaulescens* by lighter pigmentation of staminal filaments, anthers, and stigmas and by its petals lacking a basal spot. *Geranium subacutum* appears to be a somewhat variable species. Three collections from Gümüşane in northeastern Turkey (*Sintenis 5694*, *Stainton 8385*, and *Bourgeau 61*) are here included with hesitation. They have very dark purple staminal filaments and stigmas, and sometimes also spotted petals. Davis & Roberts (1955: 22) considered Gümüşane collections to be *G. subcaulescens* s.str., whereas Freyn annotated them with the nomen nudum *G. subcaulescens* f. *purpureo-violacea*. These plants grow at the northeastern limit of the range of *G. subacutum*, where *G. ponticum* also occurs. On the other hand, specimens from Sana dağı, Lâdik, and Ak

dağı, in central Turkey (near Amasya) occasionally have leaves with undivided segments and white flowers. Bornmüller named this variant var. *leucophaeum*. Some plants are much like *G. thessalum*, but they differ in that their sepals have long hairs. After studying several collections from some of these localities, I consider the occurrence of undivided leaf segments as an unusual deviation in *G. subacutum*. Peşmen & Güner (1978: 36) characterized *G. cinereum* var. *pisidicum* by petioles, pedicels, and peduncles with patent hairs; however, I found great variability in these characters in Turkish plants. On the whole, this "variety" occasionally showed more divided segments than other populations of *G. subacutum*.

Four collections are quoted in Boissier's protologue (Boissier 1867: 872). Two of them are from Mount Argaeus [Erciyes Dağı] (*Aucher 2104* and *Balansa 1036*), one from Armenia (*Bourgeau 61*), and one from the Pontic Alps (*Kotschy 788*). After examining Kotschy's collection 788 (W!), I must exclude it from the *G. subacutum*. This collection, due to its more deeply divided, almost glabrous leaves, and its very dark-purple spotted petals, staminal filaments, and stigmas, should be assigned to *G. ponticum*. Boissier (1888: 141) excluded the glabrescent plants (f. *glabrescens* Boiss., nom. nud.) found in the Pontic mountains from the circumscription of *G. subacutum* but without formal description of this form. *Bourgeau 61*, with its very dark purple staminal filaments, is a deviant form of *G. subacutum*. These plants grow at the northeastern limit of the species' range, where they coexist with *G. ponticum*, which perhaps has influenced them. However, according to Davis & Roberts (1955: 22) *Bourgeau 61* is *G. subcaulescens* s.str. These authors consider the other collection from Mount Argaeus (*Aucher 2104*) an intermediate form between *G. subcaulescens* and *G. subacutum*. I believe that all the Argaeus collections are homogeneous and belong to *G. subacutum*.

**15. *Geranium petri-davisii*** Aedo, *Anales Jard. Bot. Madrid* 52(1): 105. 1994. *Geranium cinereum* var. *elatum* P.H. Davis, *Notes Roy. Bot. Gard. Edinburgh* 28: 36. 1967, ["*elatus*"]. TYPE LOCALITY: "Turkey: B6 Maraş: d. Göksun, Hübek Dağ, 2000 m, among shady rocks, Davis 20169 (holo. E! iso. K!)". TYPE: Turkey. Kahramanmaraş, Göksun, Hübek Dağ, 37°50'N, 36°32'E, 21 July 1952, *P.H. Davis, L.G. Dodds & D. Çetik* 20169 (holotype, E!; isotypes, BM!, F-0060434F!, K!, LD!, LE!).

*Perennial herbs*, 30-50 cm tall. *Rootstock* 10-15 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves alternate in middle of shoot, the upper 1-3 pairs opposite; leaf laminas 3.5-5 cm long, 3.5-6.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.7], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5-7, in 1 plane, middle segment obtriangular, 2-3 mm wide at the base [ratio segment width at the base/middle segment length = 0.18-0.31], 3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.14-0.29]; petioles up to 29 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, not appressed, eglandular hairs 0.2-0.4 mm long; stipules 7.1-15 mm long, 1.9-3 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-3-flowered, usually in aggregates at the top of each branch [ratio cymule length/leaf length = 2-4]; peduncles 30-75 mm long, with usually retrorse, not appressed, eglandular hairs ca. 0.2 mm long; bracteoles 3-4 mm long, 1-1.5 mm wide, lanceolate,

whorled; pedicels 20-35 mm long, with retrorse, not appressed, eglandular hairs 0.2-0.4 mm long. Flowers actinomorphic. *Sepals* 10-12 mm long, 3-3.2 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 0.7-1 mm long [ratio mucro length/sepal length = 0.04-0.12], with  $\pm$  patent, eglandular, hairs 0.2-0.3 mm long on the abaxial surface (ca. 1 mm on the margin), glabrous adaxially. *Petals* 14-17 mm long, 10-11 mm wide, erect-patent, emarginate (notch 2-2.5 mm deep), without claw, purple (without a dark basal spot), glabrous on both surfaces, ciliate on the basal margin, with hairs 0.5-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4-5 mm long, lanceolate with an abruptly narrowed apex, dark purple, pilose on the abaxial surface, ciliate on the proximal third, with hairs up to 0.2-0.3 mm long; anthers 2-2.5 mm long, yellow or dark purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5-6 mm long, dark purple. *Fruit* 40-42 mm long, erect, discharge of *Erodium*-type; mericarps 8-10 mm long, 2-3 mm wide, without a strand of fibers, compressed at the apex, with 1-2 transverse ribs at apex, with basal beak 1.5-2 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.7-0.8 mm long; rostrum 29-30 mm long, without a narrowed apex, not twisted, with  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 2 mm long, with 5 glabrous lobes. *Seeds* 4-5 mm long, 2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 76.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower in July.

*Distribution*. This species is endemic to central-eastern Turkey (Fig. 77).

*Habitat*. Among shaded rocks; ca. 2000 m.

*Discussion*. *Geranium petri-davisii* is known only from the type locality in central Turkey. It is unusual within sect. *Subacaulia* in its  $\pm$  erect stem (without cymules arising from the rootstock), alternate lower cauline leaves, and ter-

Fig. 76. *Geranium petri-davisii*. a. Habit. b. Leaf. c. Portion of peduncle. d. Sepal. e. Apex of sepal. f. Petal. g. Staminal filament of outer whorl. h. Staminal filament of inner whorl. i. Mericarp subtended by calyx (two sepals removed). (Based on: Davis & al. 20169, E).

Fig. 77. Distribution of *Geranium petri-davisii*.

minal cymules grouped in 2's and/or 3's and umbel-like. I include it in sect. *Subacaulia* because of its erect-patent, emarginate petals, short inflorescence glands, and some micromorphological characters (features of the hairs and mericarp surface). *Geranium petri-davisii* does not show close resemblance to any other species of the section and is easily distinguished from them.

# 16. *Geranium palmatipartitum*

(Hausskn. ex R. Knuth) Aedo, Anales Jard. Bot. Madrid 52(1): 105. 1994. *Geranium cinereum* var. *palmatipartitum* Hausskn. ex R. Knuth in Engl., Pflanzenr. ly. *Cymules* 2-flowered, solitary [ratio cymule length/leaf length = 1.3-1.5]; peduncles 35-80 mm long, with usually patent, eglandular hairs 0.3-0.7 mm long; bracteoles 4-5 mm long, 0.4-1 mm wide, linear-lanceolate, whorled; pedicels 20-50 mm long, with usually patent, eglandular hairs 0.5-0.7 mm long. Flowers actinomorphic. *Sepals* 9-12 mm long, 3-4 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 1.2-2 mm long [ratio mucro length/sepal length = 0.07-0.15], with  $\pm$  appressed, eglandular hairs 0.2-0.5 mm long on the abaxial surface (0.7-1.7 mm long on the margin), glabrous adaxially. *Petals* 16-17 mm long, 10-11 mm wide, erect-patent, slightly emarginate, without claw, purple (without a dark basal spot), glabrous on both surfaces, ciliate on the basal margin, with hairs 0.5-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6-8 mm long, lanceolate with an abruptly narrowed apex, purple, pilose on the abaxial surface, ciliate on the proximal third, with hairs up to 0.2-0.3 mm long; anthers 3 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 7-8 mm long, dark purple. *Fruit* 33-35 mm long, erect, discharge of *Erodium*-type; mericarps 6.2-7 mm long, 2-2.6 mm wide, without a strand of fibers, compressed at the apex, with (0)1 transverse rib at apex, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 1-1.5 mm long; rostrum 23-26 mm long, without a narrowed apex, not twisted, with  $\pm$  appressed, eglandular hairs 0.3-0.4 mm long; stigmatic remnants 1.5-2 mm long, with 5 hairy lobes. *Seeds* unknown. Cotyledons not studied. Fig. 78.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from May to June.

*Distribution*. This species ranges through central-eastern Turkey (Fig. 79).

*Habitat*. Rocky places; 1800-1950 m.

*Additional specimens examined*.

**Turkey.** KAHRAMANMARAŞ-SIVAS: Afsin, Güvek Yaylasi, Armuth Pinarin Karsisi,

38°21'N, 36°32'E, 20 June 2000, İlçim 986 (MA). TOKAT: T?ha?nlübel [Çamlıbel?] Siwas et Tokat, 40°5'N, 36°31'E, 31 May 1890, Bornmüller 1973 (JE).

*Discussion.* *Geranium palmatipartitum* is one of the most distinctive species of the section by virtue of its leaves, which usually have elliptic entire segments. Information on fruit morphology is based only on one unripe fruit of *Sintenis* 2481 (JE).

İlçim & Behçet (2006) described *G. kalenderianum*, a new species related to *G. palmatipartitum*. I have examined a specimen from the type locality that fall well within the range of variability of *G. palmatipartitum*.

I could not find any type material of *G. palmatipartitum* in the Berlin herbarium, although Davis & Roberts (1955: 23) referred to it. Later, Davis (1967: 472) noted the existence of type material only in the Edinburgh and Kew herbaria.

*Discussion*. *Geranium makmelicum* is characterized by its sepals, which have a very short mucro or even lack it, and dark-yellow anthers. It is an isolated species probably related to *G. subacutum*. Dinsmore in Post (1896:

Fig. 80. *Geranium makmelicum*. a. Habit. b. Leaf. c. Base of the stem. d. Bracteoles. e. Sepal. f. Petal. g. Flower without petals and sepals. h. Stamen. i. Mericarp. j. Fruit. k. Seed. (Based on: *Gombault* 1143, MA).

Fig. 81. Distribution of *Geranium makmelicum*.

190-191) distinguished two taxa from Lebanon: plants with purple flowers (*G. subcaulescens* s.str.) and plants with white flowers (var. *obtusilobum* Bornm.). All material I studied (including Post's collections: BM!, G!) has white or pink flowers (without a dark basal spot) and dark yellow staminal filaments. Therefore no Lebanese plant can be included in the Balkan *G. subcaulescens* s.str., which has petals with a dark basal spot and very dark purple staminal filaments. All the material examined was from the Lebanese mountains except for Ehrenberg's collection (C!, K!, LE!) labeled: "Syria: ad Kafram juxta mi[?]js." I have found a similarly spelled Syrian locality: "Kafroun" (34°52'N, 36°14'E), but it is at too low an elevation for a mountain plant. Furthermore, neither Post (1896: 190-191) nor Dinsmore in Post (1932: 255-256) nor Mouterde (1966: 435-436) nor Zohary & al. (1983: 1), reported this taxon outside of Lebanon. On the other hand, Yeo (1985: 174) noted "Lebanon, Syria" for the range of this species.

**18. *Geranium ponticum*** (P.H. Davis & J. Roberts) Aedo, Anales Jard. Bot. Madrid 52(1): 106. 1994. *Geranium cinereum* var. *ponticum* P.H. Davis & J. Roberts, Notes Roy. Bot. Gard. Edinburgh 22: 23. 1955. TYPE LOCALITY: "Prov. Rize: region alpine superieure du Lazistan, au dessus de Djmil [Cimil], ver 2800 m., Balansa 1369 (K!)". TYPE: Turkey. Lazistan, au dessus de Djmil, 2800 m, 39°40'N, 40°40'E, July 1866, B. Balansa 1369 (holotype, K-000729269!; isotypes, G-00370306!, JE!, LE-00014585!, P-00757918!, RO!, US-00624268 image!, W!).

*Perennial herbs*, 5-30 cm tall. *Rootstock* 5-16 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, scapiform or subscapiform, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed,

eglandular hairs 0.1-0.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1-2(4) pairs, opposite; leaf laminae 1.8-3.6 cm long, 2.3-3.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.8], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose above, with appressed, eglandular hairs and almost glabrous abaxially; segments 5(7), in 1 plane, middle segment obtriangular, 3-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.25-0.29], 5-8-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.35]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; stipules 5-8 mm long, 1.2-2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 2-flowered, solitary [ratio cymule length/leaf length = 1.60-1.75]; peduncles 25-90 mm long, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; bracteoles 5-6 mm long, 0.7-1 mm wide, lanceolate, whorled; pedicels 25-40 mm long, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long. Flowers actinomorphic. *Sepals* 6-7.5 mm long, 3.5-4 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 1.4-2.5 mm long [ratio mucro length/sepal length = 0.14-0.16], with ± appressed, eglandular hairs 0.1-0.2 mm long on the abaxial surface (1-1.1 mm long on the margin), glabrous adaxially. *Petals* 11-13 mm long, 10-11 mm wide, erect-patent, slightly emarginate (notch 0.3-0.6 mm deep), without claw, purple (with a dark basal spot), glabrous on both surfaces, ciliate on the basal margin, with hairs 0.4-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.5-6 mm long, lanceolate with an abruptly narrowed apex, dark purple, pilose on the ab-

axial surface, ciliate on the proximal third, with hairs 0.2-0.3 mm long; anthers 1.9-3 mm long, dark purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5-6 mm long, dark purple. *Fruit* 28-30 mm long, erect, discharge of *Erodium*-type; mericarps 6-7 mm long, 2.3-2.5 mm wide, without a strand of fibers, compressed at the apex, with 1-2 transverse ribs at apex, with basal beak 1-1.5 mm long, with a basal callus, without a basal prong, brown, with ± appressed, eglandular hairs 1-1.4 mm long; rostrum 21-24 mm long, without a narrowed apex, not twisted, with ± appressed, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 2-2.5 mm long, with 5 glabrous lobes. *Seeds* 3.3-3.9 mm long, 1.5-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 82, 83.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 26?$

*Phenology*. Collected in flower from June to August.

*Distribution*. This species ranges through northeastern Turkey (Fig. 84).

*Habitat*. Grassy or rocky places, usually on granite; 1850-3000 m.

*Additional specimens examined*. **Turkey**. Lazistan, *Aucher-Éloy* 2106 (G, FI). **Discussion.** *Geranium ponticum* occurs at high elevations in the Pontic Alps of northeastern Turkey. This species has more deeply divided leaves than the others of sect. *Subacaulia*; only one other Turkish species (*G. lazicum*) and two Spanish ones (*G. subargenteum* and *G. dolomiticum*) have similar leaves. Both Turkish taxa differ from the Spanish ones by the pres-

ence of a basal callus on the mericarp. *Geranium ponticum* is distinguished from *G. lazicum* by its abaxially glabrous leaves (except on veins), very dark purple staminal filaments, and petals with a very dark basal spot. Boissier (1888: 141) proposed a name without description (f. *glabrescens*) for *Balansa* 1369; the same collection has been used by Davis & Roberts (1955: 23) to typify their var. *ponticum*. The chromosome number  $2n = 26$  attributed to this species (Martin & al. 2022) should be confirmed.

anthers; filaments 4.5-5.5 mm long, lanceolate with an abruptly narrowed apex, yellow, pilose on the abaxial surface, ciliate on the proximal third, with hairs 0.1-0.3 mm long; anthers 2 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5-6 mm long, yellow. *Fruit* 27-29 mm long, erect, discharge of *Erodium*-type; mericarps 7 mm long, 2 mm wide, without a strand of fibers, compressed at the apex, with 1-2 transverse ribs at apex, with basal beak 0.7-0.8 mm long, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.2-0.8 mm long; rostrum 20 mm long, without a narrowed apex, not twisted, with  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 2 mm long, with 5 glabrous lobes. *Seeds* 3.5 mm long, 1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 85.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to August.

*Distribution*. This species ranges through northeastern Turkey (Fig. 86).

*Habitat*. Grassy or rocky places, usually on granite; 2500-3100 m.

*Additional specimens examined*. **Turkey**. Rize: Anjer, S of Rize, 40°35'N, 40°31'E, 29 July 1934, *Balls* 1669b (BM, E, K); prov. Rize, distr. İkizdere, çermanin Tepe above Cimil, 40°38'N, 40°53'E, 29 Aug. 1952, *Davis & Dodds* 21067 (BM, E, LE); Kaçkar Dag, Uffes? Kauron valley, 40°50'N, 41°10'E, 2

July 1963, *Grod?* 16 (K); Rize province, region of Kackar-Dag, N side of the range, 40°50'N, 41°10'E, 23 Aug. 1969, *Riddley & al.* s.n. (K); A8 Rize, Çamlıhemsin, Yukari Kavrum yaylası, Mezevit-Kaçkar arası, 40°55'N, 41°11'E, 9 Aug. 1980, *Güner* 2869 (HUB).

*Discussion*. *Geranium lazicum* is probably closely related to *G. ponticum*. Both species grow in a small area of northeastern Turkey and have more deeply divided leaves than other taxa of the eastern Mediterranean region. *Geranium lazicum* is distinguished from *G. ponticum* by its petals, which lack a basal spot, and its leaves, which are pilose above and sericeous below. I was not able to locate the type material for this species. Mikhailovski's collection, cited by Woronow in the protologue, came from the Caucasus Mountains (now in Turkey,  $\pm$  41°12'N, 41°48'E). According to Vegter (1988: 1186) Woronow's material is deposited in LE, but I could not obtain any specimen related to the protologue from this herbarium. The neotype here chosen matches the original description, and was collected in the same region as indicated in the protologue.

Bobrov (1949: 10) refers to other interesting material that I was not able to examine: "Albov's specimens from Kramskaya Yaila are similar to the Kvakhid ones in the color of the corolla, but differ in their glabrous leaves". *Geranium lazicum* has discolorous leaves, pilose above and sericeous beneath, thus different from Albov's specimen. Grossheim (1932: 5, 1962: 10) and other authors only refer to the type.

**Id. *Geranium* sect. *Brasiliensia*** R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 46, 149. 1912. TYPE: *G. arachnoideum* A. St.-Hil. (designated by Knuth 1912: 46).

*Stem* erect, leafy, without prickles. *Cymules* 1-flowered. *Petals* erect-patent. *Cotyledons* with entire margins.

**20. *Geranium arachnoideum*** A. St.-Hil., Fl. Bras. Merid. 1: 82, tab. 20. 1825. *Discussion.* *Geranium arachnoideum* is the most distinctive species in sect. *Brasiliensia*. Its peduncles (and pedicels) bear only eglandular hairs (i.e., they lack the glandular hairs found in *G. brasiliense* and *G. glanduligerum*), and the mericarps have a long basal beak and lack transverse ribs at the apex. Knuth (1912: 150) recorded this species from northeastern Argentina near the Brazilian border (Misiones, Villa de Palmas, *Niederlein* 1268) but without any indication of herbarium. According to Barboza (1999: 756) this is a doubtful record

for the Argentinean flora. Unfortunately, no specimen supporting this record has been found.

**21. *Geranium brasiliense*** Progel in Mart., Fl. Bras. 12(2): 522. 1877. TYPE LOCALITY: "Rio de Janeiro: Glaziou 4776". TYPE: Brazil. Rio de Janeiro, Campos de Itatiaia, près du Ribeirão, 22°30'S, 44°30'W, 21 Jan. 1873, A. Glaziou 4776 (lectotype, designated by Aedo 2001a: 209, S-R-10014!; isolectotypes, C-10012686!, K!, P-00147012!, R-000008024!).

*Perennial herbs*, 40-64 cm tall. *Rootstock* 4-6.9 mm in diameter, vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, not appressed, eglandular hairs 0.2-0.3 mm long and patent, eglandular hairs 1-2 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 2.7-7.5 cm long, 3.7-8.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.73-0.86], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose mainly on the adaxial surface, with  $\pm$  appressed, eglandular hairs; segments 5(7), in 1 plane, middle segment rhombic, 3-7.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.24], 7-15-lobed in distal half [ratio secondary sinus length/middle segment length = 0.22-0.34]; petioles up to 29 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-2 mm long; stipules 2.2-8.8 mm long, 1.5-5.1 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 1-1.9]; peduncles 7-15(29) mm long, with patent, eglandular hairs 0.2-1.3 mm

long and patent, glandular hairs 0.3-0.9 mm long; bracteoles 1.1-2.5 mm long, 0.5-0.7 mm wide, linear-lanceolate, whorled; pedicels 8.8-20 mm long, with patent, eglandular hairs 0.2-1 mm long and patent, glandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* 4.4-7 mm long, 2-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.8 mm long [ratio mucro length/sepal length = 0.09-0.18], with  $\pm$  patent, eglandular hairs 0.3-1.3 mm long and  $\pm$  patent, glandular hairs 0.5-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* 4.9-8.2 mm long, 2.6-6.2 mm wide, erect-patent, rounded, without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.7-3.8 mm long, lanceolate with an abruptly narrowed apex, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.3 mm long; anthers 0.9-1 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-4 mm long, purple. *Fruit* 13-15.9 mm long, erect, discharge of *Erodium*-type; mericarps 3.5-4.5 mm long, 1-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 2 transverse veins at the apex), with basal beak ca. 0.3 mm long, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long; rostrum 7.4-9 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.2-0.3 mm long; stigmatic remnants 1.9-2.4 mm long, with 5 hairy lobes. *Seeds* 2.4-3 mm long, 1-1.4 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 89, 90.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 429).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from January to December.

*Distribution.* This species is endemic to southern Brazil (Fig. 91).

*Habitat.* Damp places, and forest edges; 2000-2500 m.

**Discussion.** *Geranium brasiliense* is found only in a small area in the Serra da Mantiqueira near Itatiaia (Rio de Janeiro), Brazil. It shares some features with *G. glanduligerum*: fusiform swollen roots, glandular vestiture of peduncles and pedicels, and mericarps with a short beak and transverse ribs at the apex. *Geranium brasiliense* has more deeply divided leaves than *G. glanduligerum*, and its petals are glabrous adaxially. The shape and color of the staminal filaments also separate the two species.

**22. *Geranium glanduligerum*** R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 150. 1912. TYPE LOCALITY: "Brasilien: St. Catharina, am Bache im Walde der Serra Geral (Ule a. 1890 n. 1717!)". TYPE: Brazil. Santa Catarina, Serra Geral, 27°40'S, 50°01'W, Dec. 1890, *E. Ule* 1717 (lectotype, designat-

ed by Aedo 2001a: 214, R!; isolectotypes, CORD-00002996!, HBG-517308!, P-00147010!).

**Perennial herbs**, 35-60 cm tall. **Root-stock** 4-7.8 mm in diameter, vertical, not tuberculate, not turnip-shaped, with thickened roots along the root-stock. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.2-2.2 mm long and patent, glandular hairs 0.4-1.2 mm long. **Basal leaves** in a persistent rosette, cauline leaves opposite; leaf laminae 2.2-5.5 cm long, 3.6-6.3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.78-0.80], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose with  $\pm$  appressed, eglandular hairs on the adaxial surface and with  $\pm$  appressed, eglandular and glandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 3.2-7.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.29], 5-13-lobed in distal half [ratio secondary sinus length/middle segment length = 0.16-0.23]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.4-2.2 mm long and patent, glandular hairs 0.4-1 mm long; stipules 3-6.2 mm long, 1.5-2.5 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 1.5-2.4]; peduncles 7-25 mm long, with retrorse, not appressed, eglandular hairs 0.2-0.3 mm long (sometimes patent, eglandular hairs up to 2 mm) and patent, glandular hairs 0.3-0.9 mm long; bracteoles 2.7-4 mm long, 0.5-1 mm wide, linear-lanceolate, opposite; pedicels absent or 9.3-25 mm long, with retrorse, not appressed, eglandular hairs 0.2-0.3 mm long (sometimes patent eglandular hairs up to 2 mm) and patent, glandular hairs 0.5-0.9 mm long. Flowers actinomorphic. **Se-**

**pals** 5.6-7 mm long, 2.5-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-0.9 mm long [ratio mucro length/sepal length = 0.10-0.17], with  $\pm$  patent, eglandular hairs 0.3-2.5 mm long and  $\pm$  patent, glandular hairs 0.4-1.5 mm long on the abaxial surface, glabrous adaxially. **Petals** 6-8.8 mm long, 4-7.1 mm wide, erect-patent, rounded, without claw, purple, hairy on the basal 1/4 of their adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.1-0.3 mm long. **Stamens** 10, both whorls bearing anthers; filaments 4-5 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.4 mm long; anthers 1-1.5 mm long, purple. **Nectaries** 5, hemispheric, glabrous. **Gynoecium** 4-5.9 mm long, purple. **Fruit** 15-18 mm long, erect, discharge of *Erodium*-type; mericarps 3.5-4.5 mm long, 1.2-2 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1-2 transverse veins at the apex), with basal beak 0.2-0.4 mm long, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.5 mm long; rostrum ca. 9 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.2-0.4 mm long; stigmatic remnants 2.5-2.6 mm long, with 5 glabrous lobes. **Seeds** 2.4-2.5 mm long, 1.1-1.5 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 92.

**Pollen.** *Geranium*-type.

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from September to March.

**Distribution.** This species ranges from northeastern Argentina to southern Brazil (Fig. 93).

**Habitat.** Marshy places and forest edges; 1200-1700 m.

*Discussion.* *Geranium glanduligerum* shares some features with *G. brasiliense*, but it is always easily identified by its leaves with glandular hairs on the abaxial surface and its petals with hairs on the adaxial surface. *Geranium glanduligerum* occurs in southern Brazil and northern Argentina. Its main range extends from southern Santa Catarina to northern Rio Grande do Sul, but it is also found in two apparently disjunct areas: 1) in northern São Paulo, ca. 600 km northeastward and 2) in Formosa province, ca. 800 km westward. More intensive collecting may fill the gaps.

## II. *Geranium* L. subg. *Geranium*, Sp. Pl.: 676. 1753.

*Fruit* of seed-ejection type. At dispersal, each single seed is launched from mericarp by the explosive recurvature of the awn, while the awn and the mericarp wall remain attached to the columella. Mericarps not compressed at the apex, with a basal callus or prong.

### IIa. *Geranium* L. sect. *Geranium*, Sp. Pl.: 676. 1753. TYPE: *Geranium sylvaticum* L. (designated by Hanks & Small 1907: 4).

*Geranium* sect. *Trygonium* Dumort., Fl. Belg.: 112. 1827. *Geranium* sect. *Columbina* W.D.J. Koch, Syn. Fl. Germ. Helv.: 140. 1835, nom. superfl. TYPE: *Geranium columbinum* L. (designated by Van Loon 1984c: 290). This previous designation was overlooked by Aedo & Muñoz Garmendia (1996: 105).

Fig. 93. Distribution of *Geranium glanduligerum*.

Fig. 92. *Geranium glanduligerum*. a. Habit. b. Leaf. c. Leaf detail showing indumentum. d. Peduncle. e. Flower. f. Sepal. g. Petal. h. Staminal filament. i. Fruit. j. Mericarp. k. Seed. (Based on: *Ule* 1717, P).

*Geranium* sect. *Hederacea* Paol. in Fiori & Paol., Fl. Italia 2: 233, 240. 1901. TYPE: *Geranium nodosum* L. (here designated).

*Geranium* sect. *Andina* R. Knuth, Bot. Jahrb. Syst. 32: 222. 1903. TYPE: *Geranium sessiliflorum* Cav. (designated by Knuth 1912: 45).

*Geranium* sect. *Incanoidea* R. Knuth, Bot. Jahrb. Syst. 32: 209. 1903. TYPE: *Geranium potentillifolium* DC. (designated by Knuth 1912: 45).

*Geranium* sect. *Biflora* R. Knuth, Bot. Jahrb. Syst. 37: 560. 1906. TYPE: *Geranium fiebrigianum* R. Knuth (= *G. fallax* Steud.) (here designated).

*Geranium* sect. *Diffusa* R. Knuth, Bot. Jahrb. Syst. 37: 559. 1906. TYPE: *Geranium harmsii* R. Knuth (here designated).

Knuth (1906: 559) when described this section only mentioned one species: *G. harmsii*, a likely synonym of *G. diffusum*. He indicated, however, that it is a section with more species (not mentioned) that are distributed by Colombia, Ecuador and Peru. It seems that he is implicitly referring to *G. diffusum*, both by description and by distribution and epithet. Despite this, the designation of *G. diffusum* as type of the section, as did Knuth (1912: 47), is not acceptable because it is not explicitly included in the prologue. Then, *G. harmsii* should be considered the type of the section.

*Geranium* sect. *Rupicola* R. Knuth, Bot. Jahrb. Syst. 37: 555. 1906. TYPE: *Geranium rupicola* Wedd. (art. 10.8).

*Leaves* and petiole without any abscission zone. *Stipules* ovate to lanceolate, entire, sometimes with a very short bifid apex. *Merica*ps with a basal callus.

---

**The Sylvaticum Group**—This group is characterized by the presence of alternate cauline leaves, free stipules, the dichasially branched inflorescence, with 2-flowered cymules solitary or in aggregates toward the apex of each branch, the petals hairy only on the base, the staminal narrow filaments, without an expanded base, and the glabrous nectaries. In general terms, *G. atlanticum* and *G. endressii* fit well within the group, although the former have hairy nectaries and the latter, solitary cymules.

**Discussion.** *Geranium albiflorum* is a perennial with a short horizontal rootstock and an erect habit. The basal leaves are in a ± deciduous rosette. The stem usually has an alternate leaf toward the middle (sometimes two nodes have alternate leaves) and opposite leaves on the inflorescence. The leaves are moderately divided. The indumentum of the lower part of the stem and petioles of basal leaves consists of appressed, eglandular hairs that are variable in density. On the inflorescence (peduncles, pedicels, sepals, etc.) both glandular and eglandular hairs are found. However, there are some individuals with only eglandular hairs (for instance, the isolecototypes of *G. albiflorum*). I consider that these glandular forms do not deserve taxonomic recognition, but other authors differ from this point of view (Troschkina 2017). The petals are white or, rarely, pale lilac with violet veins, narrow and emarginate.

*Geranium albiflorum* is close to *G. sylvaticum*. Both species share moderately divided leaves and the frequent presence of glandular indumentum. *Geranium albiflorum* is easily distinguished from *G. sylvaticum* by its shorter and narrower petals. Additionally, petals of *G. sylvaticum* are purple (except in the case of albinistic individuals) and with an entire apex, while those of *G. albiflorum* are white and emarginate. *G. albiflorum* also has shorter sepals with shorter mucro, shorter staminal filaments, shorter anthers, and shorter fruit than *G. sylvaticum*. As in *G. sylvaticum*, female individuals have been excluded from the descriptions.

Novoselova (1999: 129) designated a drawing as lectotype of *G. albiflorum* (Ledebour, Ic. Pl. Fl. Ross. 1: 6, tab. 18, 1829). However, according to the art. 9.19 of the the Shenzhen Code, Novoselova's choice should be superseded because one syntype collected by Ledebour from Altai has been located by Ivleva (2013) at LE herbarium.

*Perennial herbs*, 21-55 cm tall. *Rootstock* 5-10.7 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with napiform roots (27-105 mm long, 6-10 mm wide) along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with ± patent, eglandular hairs 0.7-2.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite (in some specimens medium cauline leaf alternate); leaf laminae (5)5.7-9.1(15) cm long, 6.8-22 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.82)0.86-0.89(0.91)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, (4)4.7-9.4(12.4) mm wide at the base [ratio segment width at the base/middle segment length = (0.11)0.12-0.14(0.23)], (25)38-73(96)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.29)0.32-0.52(0.56)]; petioles up to 41 cm long, without abscission zone, terete, not swollen, not deflexed in age, with ± patent, eglandular hairs 0.9-2 mm long; stipules 6.9-16.1 mm long, 1.6-3.6 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, usually in aggregates at the top of each branch [ratio cymule length/leaf length = (1.3)1.5-2.3(2.7)]; peduncles (16)19-38(49) mm long, with patent, eglandular hairs 0.7-1.2 mm long; bracteoles 3.1-7.1 mm long, 0.6-1.3 mm wide, lanceolate, whorled; pedicels (12)14-23(29) mm long, with patent, eglandular hairs 0.4-1.3 mm long. Flowers actinomorphic. *Sepals* (6.3)7.7-9.6(10.9) mm long, 2.8-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro (1.2)1.3-2(2.4) mm long [ratio mucro length/sepal length = 0.15-0.32], with ± appressed, antrorse, eglandular hairs 0.5-1.5 mm long on the abaxial surface, glabrous adaxially. *Petals* (16)16.4-

18.8(19.7) mm long, (8.8)10.4-12(12.4) mm wide, erect-patent, emarginate (notch 0.4-1 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-1.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.3)8.1-9.9(10.6) mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.8-2.5 mm long; anthers 2.1-2.4(2.5) mm long, dark purple. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8-9 mm long, purple. *Fruit* (28)31-37 mm long, erect, discharge of seed-ejection type; mericarps 3.6-4.5 mm long, 2.4-2.9 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.2-0.4 mm long; rostrum 20-29 mm long, with a narrowed apex 6.1-8.5 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 2-2.8 mm long, with 5 glabrous lobes. *Seeds* 2.3-2.5 mm long, 2.2-2.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with a notch on each side margin. Fig. 97, 98.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to June.

*Distribution*. This species ranges from northern Morocco, through northern Algeria to northwestern Tunisia (Fig. 99).

*Habitat*. Fields, grassy and rocky areas, *Quercus suber* L. and *Q. ilex* L. forests, on limestones, schistous or sandy soils; 350-1500 m.

**Discussion.** *Geranium atlanticum* is an erect perennial herb, with horizontal and thick rootstock. Along the rootstock it has several distinctive napiform roots, that almost touch each other. The indumentum consists of patent, eglandular hairs. The leaves are deeply divided with a rhombic middle segment that has some deep secondary sinus. The leaves are usually opposite, but in a part of the herbarium specimens examined one alternate leaf appears toward the basal third of the stem. Additional field work may reveal whether alternate leaves are constant, at least on populations, or if they are occasional. The dicty-

Fig. 99. Distribution of *Geranium atlanticum*.

sial inflorescence bears 2-flowered cymules at the first node and an aggregate of cymules (pseudoumbels) toward the apex of the branches. The petals are long and emarginate at the apex although sometimes very slightly. Staminal filaments are lanceolate and have a few long hairs. The cotyledons have a notch on each side. This feature has been found only in *G. aculeolatum* (with two notches on each side) (subg. *Erodioidea*), *G. albanum* (subg. *Robertium*), *G. aristatum* (subg. *Erodioidea*), *G. bohemicum* (subg. *Tuberosea*), and *G. divaricatum* (subg. *Robertium*).

Yeo (2002a: 69) included *G. atlanticum* in the *Sylvaticum* Group. It shares some important features with this group such as the structure of the inflorescence and the arrangement of the leaves. In contrast, *G. atlanticum* has nectaries with a tuft of hairs at the top, while the remaining species of the group have glabrous nectaries.

**25. *Geranium caeruleatum*** Schur, Enum. Pl. Transsilv.: 136. 1866. *Geranium pratense* [b] *caeruleatum* (Schur) Graebn. in Asch. & Graebn., Syn. Mitteleur. *Perennial herbs*, 20-43 cm tall. *Rootstock* 5.4-9.6 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, ± appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves alternate (usually 1) and upper opposite; leaf laminae (3.4)4.6-6.5(7) cm long, 3.4-8.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.85)0.91-0.93(0.97)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane,

middle segment rhombic, (0.7)1.8-3.1(5) mm wide at the base [ratio segment width at the base/middle segment length = (0.03)0.06-0.07(0.10)], (9)11-18(34)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.23)0.31-0.39(0.41)]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, ± appressed, eglandular hairs 0.2-0.5 mm long; stipules 6.3-12.1 mm long, 1.4-4.1 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (1.3)1.6-2.6(3.5)]; peduncles (22)24-71(94) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long; bracteoles 2.7-7.8 mm long, 0.5-1.2 mm wide, lanceolate, whorled; pedicels (11)15-24(33) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* (5.9)6.5-7.7(8.3) mm long, 2.1-3.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.7)1.2-2(2.6) mm long [ratio mucro length/sepal length = 0.11-0.35], with ± patent, eglandular hairs 0.4-2.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (11.7)13-16.5(18.2) mm long, (5.2)7-10.6(15) mm wide, erect-patent, rounded, without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments (4.8)6.1-6.7(7.7) mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.7 mm long; anthers (1.6)1.7-1.8(2.1) mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.8-7.9 mm long, deep pink. *Fruit* (19)23-26(28) mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.7 mm long, 1.4-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth (sometimes with 1-2 transverse veins at the apex),

without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.1-0.4 mm long and scattered, patent, glandular hairs 0.4-1 mm long (mainly at the top of the mericarp); rostrum 12-19 mm long, with a narrowed apex 0.5-2.7 mm long, not twisted, with ± patent, eglandular hairs 0.1-0.5 mm long and, sometimes, scattered, patent, glandular hairs 0.4-1.1 mm long; stigmatic remnants 1-3.8 mm long, with 5 glabrous lobes. *Seeds* 2.9-3.4 mm long, 1.3-2.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 100, 101.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 28, 56$ .

*Phenology*. Collected in flower from May to September.

*Distribution*. This species ranges from central Romania to Bosnia-Herzegovina, southern Albania, North Macedonia and Bulgaria (Fig. 102).

*Habitat*. Grassy slopes, rocky outcrops and megaphorb formations; 1500-2350 m.

**Discussion.** *Geranium caeruleatum* seems to be close to *G. rivulare*. They share a similar habit and inflorescence structure, deeply divided leaves, and a similar indumentum that is predominantly eglandular, except in the apex mericarp and the rostrum base where some glandular hairs are found. *Geranium caeruleatum*, however, has purple petals whereas *G. rivulare* has white petals. Additionally, some quantitative characters support the differentiation of both species, although with some overlap. *Geranium caeruleatum* has longer and wider petals and longer anthers than *G. rivulare*. In contrast, the fruit of *G. rivulare* is a bit longer, because the rostrum and the rostrum narrowed apex are longer than in *G. caeruleatum*. The areas of both species are separated by more than 700 km and no intermediate forms have been found.

**26. *Geranium endressii*** J. Gay, Ann. Sci. Nat. (Paris) 26: 228. 1832, ["Endressii"]. *Geranium palustre* subsp. *endressii* (J. Gay) Bonnier & Layens, Tabl. 58. 1894. *Geranium endressii* var. *armitageae* Turrill, Gard. Chron. ser. 3, 85: 164. 1929. TYPE LOCALITY: "Cultivated by Miss E. Armitage, Dadnor Garden, Herefordshire". TYPE: Great Britain. cultivated at Dadnor Gardens, Herefordshire, July 1928, *E. Armitage s.n.* (lectotype, here designated, BM-000603215!).

**Perennial herbs**, 21-66 cm tall. **Rootstock** 3-4.5 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.6-0.9 mm long and, sometimes, patent, glandular hairs 0.1-0.2 mm long. **Basal leaves** in a deciduous rosette, cauline leaves alternate (usually 1) and upper opposite; leaf laminas (2.9)5.4-8.3(12.1) cm long, 3.6-14.3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.69)0.80-0.85(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (3.9)9.1-13.8(16) mm wide at the base [ratio segment width at the base/middle segment length = (0.18)0.20-0.23(0.26)], (17)19-25(41)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.16)0.18-0.26(0.27)]; petioles up to 28 cm long, without abscission zone, terete, not swollen,

not deflexed in age, with patent, eglandular hairs 0.5-1 mm long; stipules 8.9-20.4 mm long, 1.5-3.9 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. **Inflorescence** a monochasial cyme or primarily dichasial with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.2)1.6-3.6(3.7)]; peduncles (63)78-110(138) mm long, with patent, eglandular hairs 0.4-0.8 mm long and patent, glandular hairs 0.1-0.6 mm long; bracteoles 5.9-10.5 mm long, 0.3-0.9 mm wide, lanceolate, whorled; pedicels (14)21-37(38) mm long, with patent, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.1-0.6 mm long. Flowers actinomorphic. **Sepals** (6.8)8.5-9.9(10.3) mm long, 2.6-3.5 mm wide, lanceolate, smooth, not accrescent, nerves (3)5, mucro (1.6)1.8-2.2(2.9) mm long [ratio mucro length/sepal length = 0.17-0.28], with ± patent, eglandular hairs 0.5-1 mm long and patent, glandular hairs 0.1-0.6 mm long on the abaxial surface, glabrous adaxially. **Petals** (16.1)18.3-23.9(25.1) mm long, (5.7)9.6-11.7(12) mm wide, erect-patent, emarginate (notch 0.5-2 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.6 mm long. **Stamens** 10, both whorls bearing anthers; filaments (4.6)6.5-7.9(8.2) mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.4 mm long; anthers (1.5)1.6-1.8 mm long, yellow to blue. Nectaries 5, hemispheric, glabrous. **Gynoecium** 5.5-8.6 mm long, purple. **Fruit** (29)34-36(38) mm long, erect, discharge of seed-ejection type; mericarps 3.7-4.2 mm long, 2.1-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 2 transverse vein at the apex), without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.5-0.7 mm long and, sometimes, patent, glandular hairs 0.1-0.4 mm long; rostrum 22-28 mm long, with a narrowed apex

3.6-5.5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long and patent, glandular hairs 0.4-0.7 mm long; stigmatic remnants 2.3-3.7 mm long, with 5 hairy lobes. *Seeds* 2.5-3 mm long, 1.5-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 103, 104.

*Pollen.* *Geranium*-type (Stafford & Blackmore 1991: 73, Velasco 1992b: 55).

*Chromosome number.*  $2n = 26?, 28$ .

*Phenology.* Collected in flower from April to September.

*Distribution.* This species is endemic to the western Pyrenees (France) and it is naturalized in Austria, Belgium,

France (lowland localities), Great Britain, New Zealand and U.S.A. (Fig. 105).

*Habitat.* Damp grassy and rocky outcrops; 950-1650 m.

*Additional specimens examined.*

*Discussion.* *Geranium endressii* is an erect perennial herb with long and thin horizontal rootstock, free stipules and long petals. The stem usually has an alternate leaf toward the basal third (sometimes two nodes have alternate leaves) and opposite leaves on the inflorescence. The leaves are shallowly divided, with a rhombic middle segment. The indumentum consists of short, spread, eglandular hairs. On the stem, peduncles, pedicels, sepals, and fruits there are also patent glandular hairs that vary in length and density. The inflorescence is dichasially arranged, with cymules that are noticeably long toward the base of the inflorescence. The sepals

Fig. 105. Distribution of *Geranium endressii*.

usually have five nerves and a long mucro. The petals have a notch at the apex and a hairy base, and the stigmatic remnants are hairy.

The affinities of *G. endressii* are not fully solved. Yeo (2002a: 61) included *G. endressii* in the *Endressii* Group, along with *G. nodosum*, *G. versicolor*, and *G. rectum*. *Geranium endressii* has alternate leaves on the middle part of the stem, which suggests that it can be more related to the *Sylvaticum* Group. Additionally, *G. endressii* shares with the species of the latter group glabrous nectaries and narrow staminal filaments. It dif-

fers, however, in the structure of the inflorescence, which is monochasial or primarily dichasial with monochasial branches, while in the *Sylvaticum* Group it is dichasial with aggregates of cymules at the top of each branch. According to Van Loon (1984b: 268) the chromosome numbers different to  $2n = 28$  attributed to this species should be confirmed.

*Geranium endressii* is a narrow endemic species known only from two natural populations (one with some subpopulations) in western Pyrenean (Lazare & Royaud 1994: 2). It is widely used in gardens and occasional or naturalized in Austria, Belgium, Great Britain, New Zealand, and U.S.A. The French lowland localities showed in the map (i.e., Finistère, *Miciol* s.n. MPU; Bayonne, *Bordère* s.n., MPU) probably also represent naturalizations. Its presence in New Zealand is based on a specimen at CHR could not be studied.

**27. *Geranium pseudosibiricum*** J. Mayer, Abh. Böhm. Ges. Wiss. 1786: 238. 1786, ["Pseudo-Sibiricum"]. *Geranium sylvaticum* subsp. *pseudosibiricum* (J. Mayer) D.A. Webb & I.K. **Discussion.** *Geranium pseudosibiricum* is similar to *G. caeruleatum* and *G. rivulare* in habit, leaf disposition, and inflorescence structure. They also share quite similar leaves, deeply divided, which differentiate this

group of species from *G. albiflorum* and *G. sylvaticum*. *Geranium pseudosibiricum* usually has an indumentum of retrorse to uncinat, eglandular hairs, except on the mericarp and rostrum where some glandular hairs are found. Some specimens, however, have patent glandular hairs on the inflorescence in a variable density, which varies within the same individual (for instance, *Raab-Straube 20144* (B)). It is interesting to note that the lectotype of *G. pseudosibiricum* has abundant glandular hairs on peduncles and pedicels. *Geranium pseudosibiricum* varies in petal color, from white to purple. The length of the sepal mucro also varies in a continuum. These features seem not to be correlated with each other, or with other characters or any particular geographical area. Thus, I consider that this variability do not deserve taxonomic recognition, but other authors differ from this point of view (Troschkina 2016).

*Geranium pseudosibiricum* is sometimes difficult to distinguish from *G. rivulare*. The most diagnostic feature is the sepal length, shorter in *G. pseudosibiricum* than in *G. rivulare*. Additionally, some quantitative characters support the differentiation of both species, although with some overlap. *Geranium rivulare* has longer petals, longer anthers, and longer bracteoles than *G. pseudosibiricum*. The areas of both species are separated by more than 3000 km. As in *G. sylvaticum* and *G. albiflorum*, female individuals have been excluded from the descriptions.

Bobrov (1949: 30) suggested that plants with white petals and without glandular hairs have a distinct geographical area and that they should be recognized as a different species, named *G. bifolium*. Peschkova (1996) considered three species: a) *G. laetum*, with glandular hairy pedicels; b) *G. bifolium*, with white petals, short sepal mucro and pedicels without glandular hairs; and c) *G. pseudosibiricum* with purple petals, long sepal mucro and pedicels without glandular hairs. As stated before, I have

found that the presence of glandular hairs is not stable and is not correlated with the petal color, the sepal mucro length, or the geographical area, suggesting that *G. bifolium* and *G. laetum* should be synonymized to *G. pseudosibiricum*.

**Discussion.** *Geranium rivulare* is a perennial with a short horizontal rootstock and an erect habit. The leaves are deeply cut into long and narrow segments. The medium cauline leaves are alternate at one or, rarely, two middle nodes, but become opposite toward the inflorescence. The flowers are actinomorphic and funnel-shaped, and the petals are

white with fine violet veins. The indumentum consists predominantly of appressed, eglandular hairs that are variable in density. They are spread on stems, both surfaces of the leaves, peduncles and pedicels, sepals, and fruits. On the apex of the mericarp, however, the presence of glandular hairs is constant and, in some cases, on the base of the rostrum.

*Geranium rivulare* is close to *G. sylvaticum* and, sometimes, it has been subordinate to the latter. Both species overlap their area in Central and Western Alps, and grow in similar habitats. In fact, they occasionally live together but no intermediate forms have been located. *Geranium rivulare* is easily identified from *G. sylvaticum* by its deeply divided leaves and the lack of glandular hairs on the inflorescence (except on the mericarp). Additionally, petals of *G. sylvaticum* are purple (except in the case of albinistic individuals), while those of *G. rivulare* are white.

The differences between *G. rivulare* and *G. caeruleatum* are addressed under the latter.

Fig. 110. Distribution of *Geranium rivulare*.

0.89(0.92)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (2.6)4.4-6.6(6.8) mm wide at the base [ratio segment width at the base/middle seg-

ment length = (0.07)0.10-0.15(0.19)], (6)9-13(16)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.20)0.22-0.30(0.36)]; petioles up to 18 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.6 mm long; stipules 5.6-10.8 mm long, 1.1-2.7 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (1.7)2-2.7(5.2)]; peduncles (18)40-56(65) mm long, with retrorse to uncinata, eglandular hairs 0.3-0.7 mm long and, sometimes, patent, glandular hairs 0.3-1.5 mm long; bracteoles 2.5-5.9 mm long, 0.6-1 mm wide, lanceolate, whorled; pedicels (8.5)18-25(31.5) mm long, with retrorse to uncinata, eglandular

hairs 0.3-0.6 mm long and, usually, patent, glandular hairs 0.6-1.1 mm long. Flowers actinomorphic. *Sepals* (8)8.1-9.6(9.8) mm long, 2.8-4.1 mm wide, lanceolate, smooth (with a small dark purple zone at the base), not accrescent, nerves 3, mucro (0.9)1.4-2(2.1) mm long [ratio mucro length/sepal length = 0.10-0.25], with  $\pm$  patent, eglandular hairs 0.5-1.1 mm long and, usually, patent, glandular hairs 0.2-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (15)16.1-20.1(21.1) mm long, (6.7)8.4-10.4(12.5) mm wide, erect-patent, emarginate (notch 0.2-1.7 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.9 mm long.

*Stamens* 10, both whorls bearing anthers; filaments (7.7)8-8.5(10) mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-1 mm long;

anthers 1.9-2.1(2.4) mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoeceum* 7-10 mm long, deep pink. *Fruit* 21-32 mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.4 mm long, 2.2-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth (sometimes with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-0.4 mm long and scattered, patent, glandular hairs 1.1-1.3 mm long (mainly at the top of the mericarp); rostrum 15.5-23.6 mm long, with a narrowed apex 2.6-6.2 mm long, not twisted, with patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.5-1.3 mm long; stigmatic remnants 2.2-3.7 mm long, with 5 glabrous lobes. *Seeds* 3.1-3.2 mm long, 1.5-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 111.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to September.

*Distribution*. This species ranges from northern Pakistan and north-western India (Jammu-Kashmir and Himachal Pradesh) (Fig. 112).

*Habitat*. Meadows, rocky outcrops and edge of *Abies* Mill., *Betula* L. and *Pinus* L. forests; 2600-4200 m.

*Additional specimens examined*. **India**.

*Discussion*. *Geranium schmidii* was described as a variety of *G. pratense*.

Fig. 111. *Geranium schmidii*. a. Habit. b. Leaf. c, d. Stipules. e. Bracteoles. f. Flower without petals and sepals. g. Sepals. h. Petal. i. Detail of the petal base. j. Stamen. k. Fruit. l. Detail of the rostrum indumentum. m. Mericarp. n. Seed. (Based on: a-j, *Schmid* 654, G; k-n, *Stewart* 13325, MO).

Fig. 112. Distribution of *Geranium schmidii*.

The former, however, has alternate leaves at the middle of the shoot, glabrous nectaries, narrow staminal filaments, and erect fruits, not opposite leaves, hairy nectaries, staminal filaments with an expanded base, and reflexed fruits as *G. pratense*. All these features strongly suggest that it belongs to the *Sylvaticum Group*. More specifically, it seems close to the subgroup comprising *G. caeruleatum*, *G. pseudosibiricum*, and *G. rivulare*, well characterized by its deeply divided leaves. *G. schmidii* is easily differentiated from all these species by its longer and emarginate petals. It has some overlap in petal length with *G. caeruleatum*, but the latter has more deeply divided leaves and only eglandular hairs on the inflorescence.

Hurrah & Wagh (2020) described a new species, *G. jainii*, as having alternate leaves at the middle of the shoot, glabrous nectaries, narrow staminal filaments, erect fruits and longer and emarginate petals. These authors compared his *G. jainii* with *G. pratense* and *G. collinum*, from which it is easily differentiated by the characters mentioned above. They also indicated that *G. jainii* differs from *G. pratense* var. *schmidii* in stipule length “the former having large stipules i.e. 6–10 mm long and the latter with ca 4 mm long stipules”. In fact, however, *G. schmidii* has stipules 5.6–10.8 mm long. Although it has not been possible to study the type, all these facts

support the synonymization of *G. jainii* to *G. schmidii*.

According to the article 53.2 of the Shenzhen Code “When two or more names of genera or species based on different types are so similar that they are likely to be confused (because they are applied to related taxa or for any other reason) they are to be treated as homonyms”. For this reason the specific epithet choose by Hurrah & Wagh (2020) is very unfortunate as it is very similar to *G. jahnii*, an accepted species from Venezuela.

*Perennial herbs*, 22-95 cm tall. *Rootstock* 4.8-12.2 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.5-2 mm long and, sometimes, patent, glandular hairs 0.2-0.8 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves alternate (usually 1) and upper opposite; leaf laminae (5.8)7.2-10.1(13.3) cm long, 7.8-16.3

cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.77)0.81-0.88(0.89)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, (5.1)5.7-12.3(16.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.10)0.12-0.17(0.23)], (16)21-29(32)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.15)0.19-0.25(0.32)]; petioles up to 30 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-0.9 mm long and, sometimes, patent, glandular hairs 0.3-0.8 mm long; stipules 6.8-17.1 mm long, 1.1-5.2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (1.2)1.7-2.7(3.3)]; peduncles (14)19-45(68) mm long, with patent to uncinat, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.2-0.9 mm long; bracteoles 1.8-6.1 mm long, 0.4-0.9 mm wide, lanceolate, whorled; pedicels (3.8)10-19(23.1) mm long, with patent to uncinat, eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 0.2-0.8 mm long. Flowers actinomorphic. *Sepals* (6.7)7.2-8.6(9.6) mm long, 2.4-3.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1)1.5-2.2(3) mm long [ratio mucro length/sepal length = 0.13-0.35], with ± patent, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.2-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.2)13-17.6(19.3) mm long, (6.3)7-10.8(12.6) mm wide, erect-patent, rounded or rarely slightly emarginate (notch 0.2-0.8 mm deep), without claw, purple, rarely white, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-0.9 mm long.

*Stamens* 10, both whorls bearing anthers; filaments (7.2)7.6-8.8(10.5) mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.7 mm long; anthers (1.6)1.7-2(2.4) mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5.8-9.7 mm long, purple. *Fruit* (22)26-30(36.8) mm long, erect, discharge of seed-ejection type; mericarps 3.4-5.1 mm long, 1.4-2.7 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 2 transverse veins at the apex), without basal beak, with a basal callos, without a basal prong, brown, with ± appressed, eglandular hairs 0.3-0.8 mm long and patent, glandular hairs 0.3-1 mm long; rostrum 16-27 mm long, with a narrowed apex (2.4)2.7-4.5(6) mm long, not twisted, with ± patent, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.3-0.9 mm long; stigmatic remnants 1.8-3.2 mm long, with 5 glabrous lobes. *Seeds* 2.7-3.4 mm long, 1.7-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 113, 114.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 468; Stafford & Blackmore 1991: 73; Velasco 1992b: 54).

*Chromosome number*.  $2n = 24?$ , c. 28, 28.

*Phenology*. Collected in flower from April to September.

*Distribution*. This species ranges from southern Greenland, through Europe and Caucasus to western Siberia (Fig. 115).

*Habitat*. Stream shores, moist meadows, rocky outcrops, forb formations, shrubby areas, *Rhododendron* L. thickets and edge of *Abies* Mill., *Betula* L., *Fagus* L., *Picea* A. Dietr. and *Pinus* L. forests; 0-3200 m.

**Discussion.** *Geranium sylvaticum* has a horizontal rootstock, giving rise to an erect aerial stem with a ± deciduous rosette of leaves. The stem usually has an alternate leaf up to the first branch point of the inflorescence, where a pair of opposite leaves is always present. The inflorescence is dichasially branched, with 2-flowered cymules on the lower nodes and an aggregate of cymules toward the apex of each branch. In these aggregates, the peduncles are usually short or absent. Sometimes, a lateral branch arises from the node of the alternate leaf. The indumentum of *G. sylvaticum* usually comprises glandular and eglandular hairs on the inflorescence, while in the lower parts of the plant it is predominantly eglandular. Some individuals are, however, fully eglandular.

Gynodioecy is found in many populations of *G. sylvaticum* from northern Europe. The predominantly hermaphroditic populations included a variable proportion (less than 27%) of female plants (Asikainen & Mutikainen 2003). Female individuals have been excluded from the descriptions because they have short petals and reduced stamens with nonfunctional anthers, which could distort the range of variation of these characters. Korhonen & al. (2004) studied how light availability affects resource allocation in *G. sylvaticum*.

*Geranium sylvaticum* is quite similar to *G. albiflorum* in leaf division, while *G. caeruleatum*, *G. pseudosibiricum*, and *G. rivulare* have more deeply divided leaves. The differences between *G. sylvaticum* and the remaining species are addressed under each of them. This group of five species shares some important features with *G. erianthum*, *G. platyanthum*, and *G. reinii*, such as a similar inflorescence structure and the alternate leaf in the middle of the

shoot. The latter are, however, well characterized by their staminal filaments with long hairs and by their fruit with a long narrowed apex.

According to Van Loon (1984b: 271) the chromosome numbers different to  $2n = 28$  attributed to *G. sylvaticum* should be confirmed.

The northernmost record of this species [Spitsbergen, King's Bay, 6 July 1935, *G. Haley s.n.* (GH)] has a doubtful status. According to A. Anderberg (*in litt.*), it may be a single adventive specimen or a mislabeling.

---

**The Erianthum Group**—This group shares some important features with the *Sylvaticum Group*, such as the presence of alternate cauline leaves, free stipules, the dichasially branched inflorescence, with 2-flowered cymules solitary or in aggregates toward the apex of each branch, the petals hairy only on the base, the staminal narrow filaments, without an expanded base, and the glabrous nectaries. However, they differ in the long hairs of the staminal filaments and the long narrowed apex of the fruit rostrum.

**Discussion.** *Geranium erianthum* is a robust perennial species, easily recognized by its cauline leaves alternate at one or, occasionally, two middle nodes that become opposite toward the inflorescence, its dichasial inflorescence ending in umbel-like aggregates at the apex of each branch, its long hairs on staminal filaments, and its eglandular and retrorse-appressed indumentum on the stem and petioles. It is the only Asian species also present on the eastern side of the Bering Strait. I agree with Novoselova (1999) who included *G. elatum*, *G. orientale*, and *G. subumbelliforme* in the synonymy of *G. erianthum*. An alternate view is that of Tsyrenova (1985a, 1985b, 1986), who distinguished these taxa as species, mainly at the base of leaf shape.

As Yeo (1992) pointed out, *G. erianthum* is quite similar to *G. platyanthum*, as both present dark purple staminal filaments covered with long hairs. However, *G. erianthum* differs in having lower stems with retrorse-appressed eglandular hairs, as

well as the more deeply divided and more acutely and profusely lobed and toothed leaves. The main and the second sinuses are deeper, and the middle segment is narrower at the base. Additionally, the sepal mucro is longer in *G. erianthum*, and the hairs of the stem and of the staminal filament are shorter. Usually, *G. erianthum* has glandular hairs restricted to the inflorescence. *Geranium platyanthum* is endemic to mainland East Asia, where *G. erianthum* also occurs. *Geranium erianthum* is also close to *G. sylvaticum*, since both share a similar inflorescence structure, alternate cauline leaves, and a similar petal indumentum. Nonetheless, *G. erianthum* has a longer narrowed apex of the rostrum and longer eglandular hairs on the staminal filaments than those that are found in *G. sylvaticum*.

TYPE LOCALITY: "Korea: Shajippo, Kannan (T. Nakai, no. 15565, Aug. 18, 1935)". TYPE: North Korea. Shajippo, Kannan, 40°20'N, 127°33'E, 18 Aug. 1935, *T. Nakai 15565* (lectotype, here designated, TI-00011252 image!).

**Perennial herbs**, 29-66 cm tall. **Rootstock** 6-11 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.6-1.5 mm long and, usually, patent, glandular hairs 0.4-1 mm long. **Basal leaves** in a  $\pm$  persistent rosette, cauline leaves alternate (usually 1) and upper opposite; leaf laminae (4.8)6.2-10.5(13.8) cm long, 6.4-16.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.60-0.75(0.78)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (10.5)17-23(34) mm wide at the base [ratio segment width at the base/middle segment length = (0.26)0.29-0.36(0.44)], (6)13-17(23)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.08)0.10-0.15(0.18)]; petioles up to 25 cm long, without abscission zone, terete, not swollen, not

deflexed in age, with patent, eglandular hairs 0.4-1.7 mm long and, usually, patent, glandular hairs 0.5-1.2 mm long; stipules 4.9-12 mm long, 1.6-3.3 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial

cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (0.7)1.2-2]; peduncles (16)22-41(54) mm long, with patent to retrorse, eglandular hairs 0.3-1.3 mm long and, usually, patent, glandular hairs 0.4-1 mm long; bracteoles 0.7-4.2 mm long,

0.4-0.9 mm wide, linear-lanceolate, whorled; pedicels (2.8)8-13(16.8) mm long, with patent to retrorse, eglandular hairs 0.3-1.4 mm long and patent, glandular hairs 0.3-1.1 mm long. Flowers actinomorphic. *Sepals* (6.4)6.9-9.3(10.8) mm long, 2.8-4 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (0.4)0.8-1.4(1.6) mm long [ratio mucro length/sepal length = 0.06-0.19], with antrorse, appressed, eglandular hairs 0.2-1.2 mm long and patent, glandular hairs 0.5-1.8 mm long on the abaxial surface, glabrous adaxially. *Petals* (10)12-18(19.1) mm long, (7.6)8.8-11.1(16.2) mm wide, erect-patent, rounded, without claw, purple or white, glabrous on the adaxial surface, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.5-1.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.1)9.9-11.6(14.9) mm long, lanceolate, dark purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 2-3 mm long; anthers 2.3-2.8(2.9) mm long, blue. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 8.9-13.1 mm long, green to dull red. *Fruit* (28)30-37(40) mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.5 mm long, 1.9-2.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-1.4 mm long and patent, glandular hairs 0.6-0.9 mm long; rostrum 23-34 mm long, with a narrowed apex 4.8-9.8 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 0.4-0.8 mm long; stigmatic remnants 2.1-2.6 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.2 mm long, 1.5-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 118.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 455 [sub *G. eriostemon*]; Lu & al. 1996: 320 [sub *G. eriostemon*]; Park & Kim 1997: 311; Tan & al. 1996: 210 [sub *G. eriostemon*]).

*Chromosome number.*  $2n = 28$ .

**Discussion.** *Geranium platyanthum* is a robust perennial plant that shares with *G. erianthum* and *G. reinii* its cauline leaves that are alternate at one or, occasionally, two middle nodes but become opposite toward

the inflorescence, its dichasial inflorescence ending in umbel-like aggregates at the apex of each branch and its long hairs on staminal filaments. The differences between *G. erianthum* and *G. platyanthum* have been addressed under the first species. *Geranium platyanthum* is quite similar to the Japanese *G. reinii* with regard to the indumentum of the stems and petioles; both species share long, patent glandular and eglandular hairs on these organs. Their leaves, however, differ significantly. Leaves of *G. reinii* are more deeply divided because the main and second sinuses are deeper. In addition, the main segment is narrower at the base in *G. reinii*. Although with some overlap, sepals, sepal mucro, staminal hairs, mericarp hairs, and stigmatic remnants are shorter in *G. platyanthum* than in *G. reinii*.

*Perennial herbs*, 41-80 cm tall. *Rootstock* 8.2-12.5 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-1.9 mm long and, usually, patent, glandular hairs 0.4-1.2 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves alternate (1-2) in middle of shoot and upper opposite; leaf laminae (7.8)9.2-10.7(12.9) cm long, 8.6-22 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.63-0.71(0.81)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, (8)12.1-18.3(29.4) mm wide at the base [ratio segment width at the base/middle segment length = (0.12)0.18-0.28(0.32)], 12-26-lobed in distal half [ratio secondary sinus length/middle segment length = (0.12)0.17-0.24(0.31)]; petioles up to 44 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-1.8 mm long and, usually, patent, glandular hairs 0.4-1.3 mm long; stipules 4.5-15.5 mm long, 2-6.3 mm wide, lanceolate, free, papery, brownish red,

with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (0.7)0.8-2.5]; peduncles (26)38-53(82) mm long, with patent to retrorse, eglandular hairs 0.2-2.2 mm long and patent, glandular hairs 0.4-2.4 mm long; bracteoles 2.1-6.4 mm long, 0.6-1.5 mm wide, linear-lanceolate, whorled; pedicels 11.7-26.1 mm long, with patent to retrorse, eglandular hairs 0.2-1.2 mm long and patent, glandular hairs 0.3-1.6 mm long. Flowers actinomorphic. *Sepals* (7.4)8.3-10.4(11.1) mm long, 3-5.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.1)1.6-2.6(2.7) mm long [ratio mucro length/sepal length = 0.15-0.31], with antrorse, appressed, eglandular hairs 0.3-0.7 mm long and patent, glandular hairs 0.7-1.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.5)13.5-16.4 mm long, (8.5)9.9-11.1(11.8) mm wide, erect-patent, rounded, without claw, purple or white, glabrous on the adaxial surface, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.7-1.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments (9.4)11.4-12.3(15.3) mm long, lanceolate, dark purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 1.4-4.2 mm long; anthers 2.5-2.7(2.8) mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 8.3-15 mm long, purple. *Fruit* 29.2-40.3 mm long, erect, discharge of seed-ejection type; mericarps 4.1-5.1 mm long, 1.7-2.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.3-1.2 mm long and patent, glandular hairs 0.6-2.8 mm long; rostrum 22-31.9 mm long, with a narrowed apex 5.9-11.4 mm long, not twisted, with ± patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.6-1.4 mm long; stigmatic remnants 2.7-3.8 mm long, with 5 glabrous lobes. *Seeds*

3-3.4 mm long, 1.8-2.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 120.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from May to October.

*Distribution*. This species ranges through Honshū to Hokkaidō, in central and northern Japan (Fig. 121).

*Habitat*. Grassy and rocky places; 1000-2600 m.

*Additional specimens examined. Japan.*

*Discussion.* *Geranium reinii* is quite similar to *G. platyanthum* of mainland China with regard to the indument of the stems and petioles: both species share long, patent glandular and eglandular hairs on these organs. Their leaves, however, differ significantly. The leaves of *G. reinii* are more deeply divided with deeper main and second sinuses. In addition, the main segment is narrower at the base in *G. reinii*. Although the measurements overlap somewhat, the lengths of sepals, sepal mucro, staminal hairs, mericarp hairs, and persistent stigma lobes are consistently greater in *G. reinii* than in *G. platyanthum*. Consequently this endemic form deserves specific status, although Japanese authors have traditionally preferred to treat it at the varietal rank (Akiyama 2001; Ohwi 1965). *Geranium reinii* shares with *G. erianthum* some important features, such as the one or two alternate cauline leaves (becoming opposite toward the inflorescence), the dichasial inflorescence ending in umbel-like aggregates at the apex of each branch, and the long hairs on staminal filaments. Both species are partially sympatric in Japan: *G. reinii* occurs in Hokkaidō and Honshū while *G. erianthum* is present on Hokkaidō and in northern Honshū as well. *Geranium reinii* is easy to differentiate from *G. erianthum*, however, owing to the patent glandular and eglandular indument of the stem and petioles. In both species the leaves are more

Fig. 121. Distribution of *Geranium reinii*.

deeply divided than in *G. platyanthum*. In *G. erianthum*, however, the main sinus is even deeper than in *G. reinii*. Thus the leaves of *G. reinii* are somewhat intermediate between those of *G. erianthum* and *G. platyanthum*.

**The Pratense Group**—This group is characterized by its opposite cauline leaves, its free stipules, 2-flowered cymules, the petals hairy only on the base, the staminal filaments with an expanded base and the nectaries with a tuft of hairs at the top.

*Geranium pratense* and *G. saxatile* form a subgroup well defined by the reflexed fruits when immature, and dichasial inflorescences. Yeo (2002a) recognized a “Collinum Group” that is here subsumed within the *Pratense Group*.

**Perennial herbs**, 18-61(100) cm tall. **Rootstock** 6-14.1 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long and, sometimes, patent, glandular hairs 0.2-1.3 mm long. **Basal leaves** in a ± deciduous rosette, cauline leaves opposite; leaf laminas (1.6)3-5(9.7) cm long, 1.9-11.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.76)0.80-0.85(0.90)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, (1.6)3.1-6(8.4) mm wide at the

base [ratio segment width at the base/middle segment length = (0.09)0.13-0.17(0.25)], (4)7-10(13)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.23-0.29(0.48)]; petioles up to 37 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long and, sometimes, patent, glandular hairs 0.5-0.8 mm long; stipules 2.4-15 mm long, 0.9-2.1 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1)-2-3.6(10.4)]; peduncles (26)48-107(230) mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long and, sometimes, patent, glandular hairs 0.2-0.8 mm long; bracteoles 2.3-7.5 mm long, 0.4-1.2 mm wide, lanceolate, whorled; pedicels (5.6)18.7-36.2(52.4) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long and, sometimes, patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* (4.8)6.2-7.4(9.3) mm long, 1.9-4.4 mm wide, lanceolate, smooth, not accrescent, nerves 3(5), mucro (0.7)0.9-1.6(2.8) mm long [ratio mucro length/sepal length = 0.11-0.38], with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.5 mm long and, sometimes, patent, glandular hairs 0.3-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.3)9.9-14.1(17.9) mm long, (3.9)5-9(11.8) mm wide, erect-patent, rounded, without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments (3.9)5.8-7.5(10.9) mm long, lanceolate with a broad triangular base and an abruptly narrowed apex, pink, glabrous except for a some cilia 0.1-0.6 mm long on the proximal half; anthers (0.9)1.6-2.2(3.1) mm long, yellow or pink. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3.5-10.6 mm long, pink. *Fruit* (21.7)24-29(31.7) mm long, erect, discharge of

seed-ejection type; mericarps 2.6-4.3 mm long, 1.2-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth (usually with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-0.6 mm long and, rarely, patent, glandular hairs 0.5-0.7 mm long; rostrum 15.7-23.8 mm

long, with a narrowed apex 2.8-7.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and, rarely, patent, glandular hairs 0.4-0.7 mm long; stigmatic remnants 1.3-2.5 mm long, with 5 glabrous lobes. *Seeds* 2.4-2.9 mm long, 1.4-1.8 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 122, 123.

*Discussion.* *Geranium collinum* is an erect perennial herb with leaves of medium size, short petals, staminal filaments with an expanded base, and erect fruits. The rootstock is usually ± horizontal and with thickened roots along it. The presence of glandular hairs varies considerably. Some specimens have abundant glandular hairs on the stem base, petioles, and inflorescence, while others have only few or no glandular hairs on the inflorescence. The inflorescence of well-developed specimens is monochasially arranged. The peduncles are noticeably long in the basal nodes. In small specimens, these basal peduncles can be as long as the whole plant.

This species is usually difficult to differentiate from *G. pratense* and *G. saxatile* if fruits are not available. *Geranium pratense* and *G. saxatile* have fruits reflexed in the early stage of development, while *G. collinum* has erect fruits. Leaves of *G. collinum* are usually with five segments, and they are shorter and less divided than *G. pratense* and *G. saxatile*. Additionally, sepals, petals, staminal filaments, and fruits are also shorter in *G. collinum* than the previously mentioned species, although with some overlap.

The small specimens with long peduncles are especially common in Asian mountains. Their general appearance is quite different from plants in the lowlands of Europe, but are connected by a continuum of intermediates, which suggests that they do not deserve taxonomic recognition.

The date indicated in the prologue of *G. benedictoi* is "July 1895" while the one that appears on C. Pau's label is "VII 1896". This inconsistency may be due to a labeling error of the plants sent by J. Benedicto. The *Notas Botánicas* was published by C. Pau in 1896 [according to G. López (2001), perhaps in the last third of the year], with a prologue dated July 16, 1895. The time period to study plants collected in "VII 1896", write about them and publish them that same year is too small, which would support that the actual collection date is "July 1895". Herbarium of C. Pau was integrated into MA and the sheet MA-71472 is the only one consistent with the prologue, which would further support that the inconsistency in the date would be a mere error.

*Geranium lahulense* V. Wagh & Hurrah, Phytotaxa 452(1): 76, 78 fig. 2, 79 fig. 3, 80 fig. 4. 2020. TYPE LOCALITY: "INDIA, Himachal Pradesh: Lahul & Spiti, on way to Keylong from Koksar, 32.50440° N, 77.04940° E, 3195m. 25 July 2018, Imtiyaz A. Hurrah & Rayees A. Ione 319706 (holotype: LWG!)". TYPE: India. Himachal Pradesh: Lahul & Spiti, on way to Keylong from Koksar, 32°30'N, 77°02'E, 25 July 2018, *I. Hurrah & R.A. Ione 319706* (holotype, LWG image!).

*Perennial herbs*, 23-84(150) cm tall. *Rootstock* 7-17 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-1.7 mm long and, sometimes, patent, glandular hairs 0.4-1.2 mm long. *Basal leaves* in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminae (4.2)7-10.6(16.5) cm long, 5-19.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.81)0.87-0.91(0.94)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments (5)7(9), in 1 plane, middle segment rhombic, (2.2)4-6.3(10.7) mm wide at the base [ratio segment width at the base/middle segment length = (0.05)0.07-0.10(0.17)], (10)16-23(28)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.19)0.27-0.35(0.44)]; petioles up to 61 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse to patent, eglandular hairs 0.2-0.9 mm long and, sometimes, patent, glandular hairs 0.4-1.1 mm long; stipules 6.7-19.6 mm long, 1.5-5.5 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.8)1.8-2.5(4.4)]; peduncles (13)33-73(103) mm long, with patent to retrorse, eglandular hairs 0.1-0.9 mm long and, usually, patent, glandular hairs 0.4-1 mm long; bracteoles 4.5-15.3 mm long, 0.5-2.3 mm wide, lanceolate, whorled; pedicels (2.7)8-13.7(25.9) mm long, with patent to retrorse, eglandular hairs 0.1-0.4 mm long and patent, glandular hairs 0.3-1.2 mm long. Flowers actinomorphic. *Sepals* (6.7)8.8-10.1(11) mm long, 2.8-5.4 mm wide, lanceolate, smooth, not accrescent, nerves (3)5, mucro (1.7)2.3-3.1(4.3) mm long [ratio mu-

cro length/sepal length = 0.17-0.43], with patent eglandular hairs 0.2-0.8 mm long and patent glandular hairs 0.2-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.6)14.8-19.2(22.6) mm long, (7)9-13(16.4) mm wide, erect-patent, rounded, without claw, blue, sometimes purple or white, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.2)8.7-10.3(10.7) mm long, lanceolate with a broad triangular base and an abruptly narrowed apex, pink to dark violet, glabrous on the abaxial surface, ciliate on the proximal third, with hairs 0.1-0.6 mm long; anthers (1.8)2.2-2.6(3.1) mm long, dark violet to blue black. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6.3-13.3 mm long, pink to dark purple. *Fruit* (29)32-35(37.8) mm long, reflexed when immature, discharge of seed-ejection type; mericarps 3.5-5.4 mm long, 1.3-2.5 mm wide, without a strand of fibers, not compressed at the apex, smooth (usually with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  appressed eglandular 0.2-0.8 mm long and patent glandular hairs 0.4-1 mm long (mainly at the apex); rostrum 22-29 mm long, with a narrowed apex 4.8-9.9 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and patent, glandular hairs 0.3-1 mm long; stigmatic remnants 2-3.4 mm long, with 5 glabrous lobes. *Seeds* 2.7-3.6 mm long, 1.5-2 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 125, 126.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 429; Gagnepain 1903: 88 [sub *G. affine*]; Lu & al. 1996: 320; Park & Kim 1997: 311; Stafford & Blackmore 1991: 70; Tan & al. 1996: 210; Velasco 1992b: 54).

*Chromosome number*.  $2n = 24?$ ,  $26?$ ,  $28$ ,  $28+B$ .

*Phenology*. Collected in flower from April to October.

*Distribution*. This species ranges through Europe (from Ireland to Ural Mountains) and Asia (from Caucasus and Turkey to eastern Siberia, through Afghanistan, northern India, Nepal, China, Kazakhstan and Mongolia) and it is introduced in southeastern Canada and northwestern U.S.A. (Fig. 127).

*Habitat*. Roadsides, fields, waste grounds, dunes, damp meadows and edge of deciduous or mixed forests; 0-4300 m.

*Representative specimens examined*. **Andorra**. SAN JULIÀ DE LÒRIA: de borda del Sabater a Tolse, 42°26'N, 1°28'E, 27 Aug. 2002, Aedo & al. 8446 (MA). **Armenia**. **Discussion.** *Geranium pratense* is a robust species with a well-developed ± horizontal rootstock covered by thickened roots. The leaves are normally of great size, opposite, deeply divided, and usually with seven seg-

ments that are clearly distinguishable. The degree of division of the leaves is variable throughout the area of the species. The pedicels are usually short and more or less reflexed, at least when the fruits are immature. The sepals have a long mucro. Petal size and color are also highly variable. This species usually has blue petals, but more or less dark purple or even white petals can be found. Staminal filaments color and stigma color also vary in a similar way, with the occasional appearance of specimens with very dark stamens and stigma. The indumentum of *G. pratense* comprises glandular and eglandular hairs on the inflorescence, while in the lower parts of the plant it is predominantly eglandular. The glandular indumentum varies sometimes in the same specimen, in which some peduncles and sepals have few or no glandular hairs.

Bobrov (1949) accepted as species two forms from the Caucasus mountains, based mainly on the color of their petals: *G. finitimum* and *G. ruprechtii*, and a form of deeply dissected leaves from Eastern Siberia and Mongolia: *G. transbaicalicum*. Novoselova (1998) in her study of Caucasian species, assumes Bobrov's treatment, adding some quantitative differences in petal length and rostrum narrowed apex length. However, she indicated that there is a significant variability of the features that could differentiate *G. pratense* from these local Caucasian forms. Peschkova (1996) recognized from Siberia a variant of white petals, *G. affine*, and some forms of *G. pratense* and *G. transbaicalicum* based on different indumentum arrangement. Yeo (2002a) considered *G. pratense* as a very variable species with some regional variants part of which were recognized with informal names (i.e., "European Form" or "Nepal Form") or accepted as species with doubts. The latter is the case of *G. transbaicalicum*, about which Yeo (2002a) indicated: "There is in fact a series of plants progressively more like the "European Form" of *G. pratense* that makes me reluctant to

accept *G. transbaicalicum* as deserving specific rank."

*Geranium pratense* is distributed over a large area with more than 8000 km between the westernmost localities in Ireland and Spain, and the easternmost in northeastern China, and consequently occurs in very different habitats and climatic conditions. This species displays a wide variability in leaf shape, indumentum and flower color. Leaf blades of *G. pratense* are deeply divided with a deeper main and second sinuses. The extreme leaf-divided forms have been segregated as *G. transbaicalicum*. However, these plants can be found along the area of *G. pratense* intermixed with normal forms. Petal color is usually bluish but it also varies from white to purplish and is not related to leaf division or other characters which suggests that it has little taxonomic importance. A continuum of intermediates suggests that these forms do not deserve taxonomic recognition. Petal size also shows a remarkable range in variation, but it is not correlated with leaf shape, petal color, or indumentum.

According to Van Loon (1984b: 270) the chromosome number  $2n = 24$  attributed to this species should be confirmed. Likewise, the number  $2n = 26$  attributed to this species (Martin & al. 2022) should be confirmed.

*Geranium pratense* is widely used in gardens and occasional or naturalized in Australia, New Zealand, Canada and U.S.A. Its presence in Australia, probably as garden-escape, is based on a specimen at AD could not be studied, while its presence in New Zealand is recorded by Webb & al. (1988: 729).

*Perennial herbs*, 9-30(48) cm tall. *Rootstock* 5.5-11 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.1-0.8 mm long and, sometimes, patent, glandular hairs 0.2-1.4 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas (1.4)3-4.4(6.2) cm long, 1.5-8.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.63)0.76-0.83(0.89)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (2)3.7-7.2(9.8) mm wide at the base [ratio segment width at the base/middle segment length = (0.12)0.17-0.24(0.41)], (6)8-13(19)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.23-0.29(0.34)]; petioles up to 28 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse to patent, eglandular hairs 0.1-0.7 mm long and, sometimes, patent, glandular hairs 0.4-1.6 mm long; stipules 3.6-11 mm long, 0.7-3.2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.1)1.8-3.7(7.4)]; peduncles (20)40-107(230) mm long, with retrorse, appressed, eglandular hairs 0.1-0.6 mm long and, usually, patent, glandular hairs 0.2-2.6 mm long; bracteoles 3.5-9.5 mm long, 0.5-1.6 mm wide, lanceolate, whorled; pedicels (1.2)5.9-21.8(83) mm long, with retrorse, uncinat, eglandular hairs 0.1-0.6 mm long and, usually, patent, glandular hairs 0.2-2.1 mm long. Flowers actinomorphic. *Sepals* (6.7)8-9.7(11.3) mm long, 2.6-4.6 mm wide, lanceolate,

smooth, not accrescent, nerves 3-5, mucro (0.6)0.9-1.6(2.5) mm long [ratio mucro length/sepal length = 0.08-0.25], with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long and usually patent, glandular hairs 0.3-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (12)15.4-21.1(27.7) mm long, (5.6)8-12(16.3) mm wide, erect-patent, rounded or rarely slightly emarginate (notch 0.3-1 mm deep), without claw, purple, glabrous

on both surfaces, ciliate on the basal margin, with hairs 0.2-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.4)8.8-10.5(14.3) mm long, lanceolate with a broad triangular base and an abruptly narrowed apex, lilac, glabrous except for a some cilia 0.1-0.5 mm long on the proximal half; anthers (1.9)2.1-2.6(2.9) mm long, dark blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous.

*Gynoecium* 6-15 mm long, purple. *Fruit* (27)29-36(37) mm long, reflexed when immature, discharge of seed-ejection type; mericarps 3.3-5.1 mm long, 1.4-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth (usually with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular 0.1-0.4 mm long and patent, glandular hairs 0.2-0.7 mm long (mainly at the top of the mericarp); rostrum 21-30 mm long, with a narrowed apex 7.7-10.9 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long and patent, glandular, hairs 0.4-0.9 mm long; stigmatic remnants 1.9-3.3 mm long, with 5 glabrous lobes. *Seeds* 2.3-3.4 mm long, 1.5-1.9 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 128.

*Pollen*. *Geranium*-type (Perveen & Gaiser 1999: 265 [sub *G. himalayense*]).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from April to October.

*Distribution*. This species ranges through Afghanistan, Pakistan, northern India (Himachal Pradesh, Jammu-Kashmir and Uttaranchal), Nepal, eastern Kazakhstan, Kyrgyzstan, Tadjikistan and Uzbekistan to western China (Xinjiang and Xizang) (Fig. 129).

*Habitat*. Meadows, river banks, grassy slopes, steep hillsides with shrubs and edge of *Picea* A. Dietr., and *Pinus* L. forests; 1900-5000 m.

*Discussion.* *Geranium saxatile* is an erect perennial herb, easily identified by its leaves of medium size and not deeply divided, its long petals, its staminal filaments with an expanded base, and its reflexed immature fruits.

The rootstock is usually  $\pm$  horizontal and with thickened roots along it. The presence of glandular hairs varies considerably. Some specimens have abundant glandular hairs on the stem base, petioles, and inflorescence, while others have only few glandular hairs on the inflorescence. The inflorescence of well-developed specimens is a dichasially arranged cyme with monochasial branches. In small specimens, the inflorescence may be reduced to one terminal cymule borne on a short stem or, in extreme cases, directly on the rootstock. The petals and the leaves vary in size considerably, being shorter in small specimens. The petals have hairs on the basal margins and, sometimes, slightly notched apex. These small specimens have been recognized taxonomically with different names (i.e., *Geranium collinum* var. *alpinum*, *G. minutum*, *G. exul*, *G. sophiae*). Novoselova (1996: 88) firstly suggested that these morphological variations are related to different habitats where *G. saxatile* occurs and, consequently, that it does not deserve taxonomic recognition. This is also supported by a continuum of intermediates.

*Geranium saxatile* is quite similar to *G. pratense*. They share the staminal filaments with a broad triangular base and an abruptly narrowed apex, the hairy nectaries and the immature reflexed fruits. The latter, however, is usually a more robust plant with longer leaf blades that have more segments, longer sepals, and longer sepal mucro, although with some overlap.

Schönbeck-Temesy (1970: 15) typified *Geranium himalayense* on an *Edgeworth's* specimen at K that is not mentioned in the protologue. Thus, according to art. 9.19 of the Shenzhen Code, this choice should be superseded. The lectotype has been selected on the drawing mentioned in the protologue because no original specimen has been located.

**The Wallichianum Group**— This group is characterized by the trailing

habit, the opposite cauline leaves, the 2-flowered cymules, the monochasially branched inflorescence, the petals hairy only on the base, the black and lanceolate (without expanded base) staminal filaments, and the black anthers and stigmas. Some species have connate stipules.

Yeo (2002a) recognized *G. rubifolium* in this group, which has been transferred to the "Other species from Eurasia", along with other species of unclear affinities.

### 37. *Geranium christensenianum*

Hand.-Mazz., Symb. Sin. 7: 621, taf. 10 abb. 2. 1933. TYPE LOCALITY: "Y.: Beyendjing, in Wäldern des Betsao-ling, 25. IX. 1919 (Ten 1392)". TYPE: China. Yunnan, silvis Pe tsao lin, 23°47'N, 105°13'E, 25 Sep. 1919, S. Tén 1392 (holotype, C-10012687!).

*Perennial herbs*, 48-100 cm tall. *Rootstock* 5-6 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, unknown roots. *Stem* trailing, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-1.3 mm long and patent, glandular hairs 0.5-1.1 mm long. *Basal leaves* unknown, cauline leaves opposite; leaf laminas 3.9-5.3 cm long, 4.8-6.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.73-0.80], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs and  $\pm$  patent, glandular hairs on both surfaces; segments 3(5), in 1 plane, middle segment rhombic, 8.6-10.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.25-0.30], 5-13-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.20]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1.1 mm long and patent, glandular hairs 0.2-1.4 mm long; stipules

4.7-11.4 mm long, 1.6-4.6 mm wide, lanceolate, free, papery, brown, with scattered, eglandular and glandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.8-2.6]; peduncles 21-153 mm long, with patent, eglandular hairs 0.2-0.9 mm long and patent, glandular hairs

0.2-1.3 mm long; bracteoles 6.3-7.8 mm long, 1-1.3 mm wide, lanceolate, whorled; pedicels 8.5-16.9 mm long, with patent, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.3-1.2 mm long. Flowers actinomorphic. *Sepals* 8.4-12.2 mm long, 3.7-4.7 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1.6-2.8 mm long [ratio mucro length/sepal

Fig. 130. *Geranium christensenianum*. a. Habit. b. Stipules. c. Leaf indumentum on adaxial side. d. Leaf indumentum on abaxial side. e. Bracteoles. f. Flower without petals and sepals. g. Sepal. h. Fig. 131. Distribution of *Geranium christensenianum*.

length = 0.19-0.22], with antrorse to patent, eglandular hairs 0.2-0.8 mm long and  $\pm$  patent, glandular hairs 0.5-1.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 12.3-13.6(16) mm long, 8-9 mm wide, erect-patent, rounded, without claw, white, with fine dark purple veins, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs ca. 1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7.8-10.2 mm long, lanceolate, black except the base, covered  $\pm$  abundantly hairs 0.2-0.8 mm long on the abaxial surface and margin, hairless towards the tip; anthers 2.1-2.5 mm long, black. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8.1-9.7 mm long, black. *Fruit* 32 mm long, erect, discharge of seed-ejection type; mericarps 4.3 mm long, 1.6 mm wide, without a strand of fibers, not compressed at the apex, smooth (sometimes with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-1 mm long and patent, glandular hairs 0.6-1.6 mm long; rostrum 21-22 mm long, with a narrowed apex 4-5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.4-1.4 mm long; stigmatic remnants 5.9-6.2 mm long, with 5 glabrous lobes. *Seeds* unknown. Cotyledons not studied. Fig. 130.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to September.

*Distribution*. This species is endemic to Yunnan, in south-central China (Fig. 131).

*Habitat*. Forest edges; 1300-1900 m.

*Additional specimens examined*. **China**. YUNNAN: distrito Chuxiong, población Dayao, pueblo Santai, 25°41'N, 101°18'E, 11 July 1965, *Pl. Oleag. Exped.* 65-0417 (KUN).

*Discussion*. *Geranium christensenianum* is only known from the holotype and an additional collection. Consequently, some features are not known or poorly described because of the scarcity of available material. This species resembles *G. lambertii* in some aspects. Both usually have white petals and black staminal filaments, anthers and stigmas, and free stipules. *Geranium christensenianum* has, however, leaf blades mostly with three segments, although some cultivated specimens could have basal leaves with five segments. Additionally, *G. christensenianum* further differs from *G. lambertii* in its shorter sepals and petals and in its glandular indumentum on the stem, petioles, and inflorescence.

**38. *Geranium lambertii*** Sweet, Geraniaceae 4, tab. 338. 1827, ["*Lamberti*"]. **Discussion.** *Geranium lambertii* is a trailing and ascending herb not rooting in the nodes. Its underground parts are poorly known through the scarce herbarium material available. One incomplete sheet shows a narrow, vertical rootstock with thickened roots. The mature stems are naked toward the base, apparently without rosette. According to Yeo (2002a: 91), *G. lambertii* is a plant with very few basal leaves. This species is easily distinguished by its densely hairy staminal filaments, which are hairless toward the tip. The staminal filaments are black especially on the upper part, as are the anthers and stigmas. *Geranium christensenianum* and *G. procurrens* also have hairy and black staminal filaments, but not as densely hairy as *G. lambertii*. Additionally, *Geranium lambertii* further differs from the previously mentioned species in its noticeably long peduncles, petals, and sepals, as well as in its free stipules and its predominantly eglandular indumentum. Scattered glandular hairs

appear on stipules and sepal base as well as on the fruit. Fruit variability is, however, poorly known because of the scarcity of available material.

*Geranium lambertii* was described from a cultivated plant raised from seeds "... that was procured by Mr. David Don, from a specimen in Mr. Lambert's Herbarium that had been sent by Dr. Wallich" from Nepal. Since no specimen of such cultivated plants has been preserved, I selected the drawing as lectotype. An epitype is also designated for purposes of the precise application of the name. According to Yeo (1973b), *Geranium backhousianum* was described from a cultivated plant raised at Leningrad from seeds obtained from England, the stock being suspected of having originated in Nepal. Apparently, none of these specimens is preserved.

---

**Discussion.** *Geranium procurrens* is a trailing herb with very long internodes and rooting in the nodes. Its underground parts are poorly known through the scarce herbarium material available. Two incomplete sheets show a narrow, vertical rootstock without roots. The mature stems are naked toward the base, apparently without rosette. Nevertheless, the lack of rosette should be confirmed in young plants. The stipules may be free or connate but with the tip remaining free. Both types can be found on the same plant. The indumentum consists of eglandular and glandular hairs, the latter are especially copious

on peduncles, pedicels and sepals. The inflorescence is formed by 2-flowered cymules, monochasially arranged. The sepals have a short mucro and are densely hairy on the abaxial surface. The petals are long, with a basal black spot, and with hairs on the base and basal margin. The staminal filaments and stigmas are black. The anthers, however, seem to be clearer on dry specimens.

*Geranium procurrens* shares with *G. wallichianum* the trailing habit and the black staminal filaments and stigmas. The former is, however, easily identified by its black basal petal spot. *Geranium procurrens* further differs from *G. wallichianum* in having narrower stipules that are never completely connate and in rooting at the nodes. As Yeo (1973b) explained in detail, the specimens of *G. procurrens* have been repeatedly confused with *G. lambertii* and its synonyms. The latter has pale pink or white petals, without a basal black spot, and more hairy staminal filaments.

**40. *Geranium wallichianum* D. Don** in Sweet, Geraniaceae 1, tab. 90. 1821. TYPE LOCALITY: "D. Don prodr. Fl. Nepalens. ined. / Habitat in Nepaliae alpihus. D. Wallich". TYPE: Nepal. **Perennial herbs**, 24-75 cm tall. **Rootstock** 2.2-18.7 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. **Stem** trailing and ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with

patent to retrorse, eglandular hairs 0.3-1.7 mm long and, rarely, scattered, patent, glandular hairs 1.4-2 mm long. **Basal leaves** not present (no rosette), cauline leaves opposite; leaf laminae (2.8)4.1-6.3(7.4) cm long, 3.5-9.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.71)0.76-0.82(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (5.5)8.6-12.5(13.9) mm wide at the base [ratio segment width at the base/middle segment length = (0.21)0.24-0.29(0.36)], (9)11-15(19)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.10)0.17-0.22(0.24)]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.4-1.5 mm long and, rarely, scattered, patent, glandular hairs 1.5-2 mm long; stipules 6.5-19.1 mm long, 4-13 mm wide, broadly ovate, connate, papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1)1.4-3.1(5.7)]; peduncles (33)66-114(153) mm long, with patent to retrorse, eglandular hairs 0.2-1.4 mm long; bracteoles 6.7-12.9 mm long, 1.3-3.7 mm wide, broadly lanceolate, whorled; pedicels (26)36-53(81) mm long, with patent to retrorse, eglandular hairs 0.2-1.5 mm long and, rarely, scattered, patent, glandular hairs 1.5-2.1 mm long. Flowers actinomorphic. **Sepals** (6.3)7.5-9.5(10.2) mm long, 2-4.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.6)2.3-3.7(4.6) mm long [ratio mucro length/sepal length = 0.20-0.58], with antrorse, ± appressed, eglandular hairs 0.6-1.5 mm long on the abaxial surface, glabrous adaxially. **Petals** (12.2)15-19.6(21.8) mm long, (6.4)9.9-12.4(17.2) mm wide, erect-patent, emarginate (notch 0.4-1.4 mm deep), without claw, deep pink to purple or blue, hairy on the base of

the adaxial surface, ciliate on the basal margin, with hairs 0.3-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.1)6.7-7.6(9.3) mm long, lanceolate, black at least at tip, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.7 mm long; anthers (1.6)2.1-2.8(3) mm long, black. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6-10 mm long, black to dark purple. *Fruit* (25)32-38(44) mm long, erect, discharge of seed-ejection type; mericarps 4.1-5.6 mm long, 1.8-2.8 mm wide, without a strand of fibers, not compressed at the apex, smooth (usually with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.6-1.6 mm long; rostrum 17-28 mm long, with a narrowed apex 2.2-4.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 2.6-7.6 mm long, with 5 usually glabrous lobes. *Seeds* 3.1-4.8 mm long, 1.6-2.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 137, 138.

*Pollen*. *Geranium*-type (Perveen & Gaiser 1999: 267).

*Chromosome number*.  $2n = 26, 28$ .

*Phenology*. Collected in flower from March to December.

*Distribution*. This species ranges from Afghanistan and Pakistan through northern India (Himachal Pradesh, Jammu-Kashmir, Uttar Pradesh and Uttaranchal) and Nepal to China (Xizang) (Fig. 139).

*Habitat*. Open fields, grassy hillsides, streams and edge of *Acer* L., *Picea* A. Dietr., *Pinus* L. and *Quercus* L. forests; 1700-4350 m.

*Representative specimens examined*.

**Discussion.** *Geranium wallichianum* is a trailing herb with thickened roots along a robust, vertical rootstock. The mature stems are naked toward the base, apparently without rosette. Nevertheless, the lack of rosette should be confirmed in young plants. This species is easily distinguished by its broadly ovate, connate stipules, present

in all nodes of the stem. They have a cordate base and an obtuse apex. The indumentum mainly consists of eglandular hairs. Rarely, scattered glandular hairs have also been found on the stem, petioles, and pedicels. The inflorescence is formed by 2-flowered cymules, monochasially arranged. The bracteoles are appreciably wide and often connate in their basal half. The sepals have a long mucro and are hairy mainly on the nerves. The petals are long, without a basal dark spot, and with hairs on the base and basal margin. The staminal filaments are black, at least toward the apex, as are the anthers and stigmas. The mericarp calyx is small and with few hairs. As Yeo (2002a: 90) indicated, the mericarps have an unusually widely open base.

*Geranium wallichianum* shares with *G. koreanum* distinctive broadly ovate stipules. They have very separate areas of distribution and some other important differentiating morphological features mentioned in the key. Additionally, *G. wallichianum* has

black filaments, anthers, and stigmas, and broad bracteoles, not found in *G. koreanum*. Knuth (1912: 195) records of *G. wallichianum* from Korea [Taquet 608 (E), Taquet 609 (E, G)] should be referred as *G. koreanum*.

Sweet (1821, tab. 90) attributed *G. wallichianum* to D. Don because he transcribed the description from Don's unpublished *Prodromus Florae Nepalensis* (Don 1825: 207), although he did not provide the specific locality where the plants were collected ("Habitat in Nepaliae alpinis. D. Wallich"). Don (1825), however, indicated a precise location for his plant: "Hab. in Gosaingthan. Wallich." Wallich (1848) mentioned under the number 8558 four collections for *G. wallichianum*: a) Sirmore G. Govan. / b) Ibid. Gerard. / c) Goshain Than, Bharut Singh. / d) Kamaon R. Blinkworth" Schönbeck-Temesy (1970: 25) right-

ly selected the type as *Wallich 8558c*, the only locality mentioned by Don (1825). Consequently, according to art. 9.19c of the Shenzhen Code, the choice of Knuth (1912: 195) of *Wallich 8558d* (B) should be superseded.

Its presence in New Zealand, probably as garden-escape, is based on a specimen at AK could not be studied.

**The Refractum Group**—This group of perennial species with thickened roots along the rootstock is characterized by the presence of opposite leaves, usually broad and connate stipules, and usually reflexed petals and immature fruits. The cymules are 2-flowered and arranged in a monochasial inflorescence.

*Perennial herbs*, 23-85 cm tall. *Rootstock* 6.9-18.1 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-0.7 mm long and, rarely, patent, glandular hairs 1-1.1 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae (3.2)4.6-7.2(10.1) cm long, 3.8-14.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.81)0.85-0.91(0.94)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (3.3)4.6-7.3(11) mm wide at the base [ratio segment width at the base/middle segment length = (0.10)0.11-0.14(0.16)], (9)13-18(26)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.17-0.23(0.33)]; petioles up to 43 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-0.9 mm long and, rarely, patent, glandular hairs 0.4-0.5 mm long; stipules 5.5-19.4 mm long, 1.8-6.3 mm wide, broadly lanceolate, connate (at least at the base), papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous

adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (1.4)2-3.9(6)]; peduncles (20)40-111(125) mm long, with patent to retrorse, eglandular hairs 0.2-0.6 mm long and, sometimes, patent, glandular hairs 1-2.1 mm long; bracteoles 2.9-14.1 mm long, 0.1-0.7 mm wide, filiform, whorled; pedicels (7.3)16-25(34) mm long, with patent to retrorse, eglandular hairs 0.2-0.5 mm long and, sometimes, patent (colourless), glandular hairs 0.9-1.5 mm long. Flowers actinomorphic. *Sepals* (6.5)7.1-8.8(10) mm long, 2.3-4.2 mm wide, lanceolate, smooth (with a small dark purple zone at the base), not accrescent, nerves 3(5), mucro (0.9)1.2-1.6(2.6) mm long [ratio mucro length/sepal length = 0.12-0.34], with antrorse, ± appressed, eglandular hairs 0.3-1.1 mm long and, sometimes, patent, glandular hairs 0.6-2.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.1)8-11(12.3) mm long, (3.2)3.9-5.5(6.6) mm wide, reflexed, rounded, with claw 0.4-1.3 mm long, blackish red to pink with a whitish base, usually hairy on the base of the adaxial surface and sometimes on the abaxial surface, with a dense tuft of hairs on the basal margin, with hairs 0.6-2.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.7)9.1-11(11.3) mm long, lanceolate, reddish purple, sparsely pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.8(1.1) mm long; anthers (1.9)2.1-2.3(2.5) mm long, blue black. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 5.5-11.7 mm long, purple. *Fruit* (23.9)24.3-28.3(29.9) mm long, reflexed when immature, discharge of seed-ejection type; mericarps 3-4.2 mm long, 1.2-1.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.2-0.8 mm long; rostrum 17-

22.1 mm long, with a narrowed apex 3.6-6.2 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.7 mm long; stigmatic remnants 1.8-3.4 mm long, with 5 glabrous lobes. Seeds 2.2-2.8 mm long, 1.1-1.8 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 140.

**Pollen.** *Geranium*-type (Bortenschlager 1967: 429; Park & Kim 1997: 312; Tan & al. 1996: 210).

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from May to October.

**Distribution.** This species ranges through south-central China (Sichuan, Xizang, Yunnan) (Fig. 141).

**Habitat.** Meadows, grassy slopes, bamboo formations and edge of *Abies* Mill., *Pinus* L., and *Quercus* L. forests; 2000-4600 m.

**Representative specimens examined.**

**Discussion.** *Geranium delavayi* share a similar habit, connate stipules, nodding flowers and immature fruits, and narrow and reflexed petals with *G. refractum* and *Geranium sinense*. The glandular hairs of the inflorescence, when present, are similar to those of *G. sinense*, as well as the filiform bracteoles and the inflorescence with aggregate of cymules toward the

apex of each branch. Leaves of *G. delavayi* and *G. sinense* have a middle segment which resembles those of *G. nodosum* or *G. versicolor*. Petals of *Geranium delavayi* are shorter than in *G. refractum* and *G. pogonanthum*, and they are blackish red to pink with a whitish base. They resemble those of *G. sinense*, but with a dense tuft of hairs on the basal margin. The almost glabrous filaments are also useful to differentiate *G. delavayi* from *G. pogonanthum*, and the distinct nectaries from *G. sinense*.

*Geranium calanthum* is sometimes differentiated by pale yellow petals. However, neither original description nor type specimen supports this opinion. *Geranium kariense* and *G. limprichtii* are differentiated by the nonglandular pedicels and petal size, which are variable features in *G. delavayi*.

**Discussion.** *Geranium pogonanthum* is a species quite similar to *G. delavayi*. Both share a similar habit, broadly lanceolate and connate stipules, nodding flowers and reflexed immature fruits, and narrow and reflexed petals. This species is difficult to differentiate from *G. delavayi* when fresh petals are not available to observe their colors. However, *G. pogonanthum* has staminal filaments with longer and abundant hairs and longer petals. Glandular indumentum is also variable in *G. pogonanthum*, being sometimes just present on the stem base and other times only on the inflorescence. Bracteoles are sometimes filiform, as in *G. delavayi*, and other times lanceolate as in *G. yunnanense*. Seed measurements are from Yeo (1992).

**Perennial herbs**, 16-58 cm tall. **Root-stock** 5-18 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with thickened roots along the root-stock. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-1.3 mm long and, rarely, patent, glandular hairs 0.7-0.8 mm long. **Basal leaves** in a persistent rosette, cauline leaves opposite; leaf laminas (3)3.5-4.8(6.8) cm long, 3.3-7.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.73)0.82-0.87(0.89)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs and, rarely, patent, glandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (2.3)4.1-5.4(7.5) mm wide at the base [ratio segment width at the base/middle segment length = (0.10)0.14-0.20(0.22)], 6-13(18)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.23-0.28(0.32)]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.3 mm long and, rarely, patent, glandular hairs 0.7-0.8 mm long; stipules 5.1-11.8 mm long, 2.6-5.6 mm wide, broadly lanceolate, connate (at least at the base), papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.1)2-4.1(5.5)]; peduncles (39)53-73(200) mm long, with uncinat and patent,

eglandular hairs 0.2-1.3 mm long and patent (purplish), glandular hairs 0.4-0.9 mm long; bracteoles 2.3-6.8 mm long, (0.4)0.6-1.1 mm wide, linear-lanceolate, whorled; pedicels (4)16-28(40) mm long, with uncinata and patent, eglandular hairs 0.4-0.9 mm long and patent (purplish), glandular hairs 0.4-0.8 mm long. Flowers actinomorphic. *Sepals* (7.4)8.8-9.3(10.8) mm long, 2.9-5.2 mm wide, lanceolate, smooth (with a small dark purple zone at the base), not accrescent, nerves 3-5, mucro (0.8)0.9-1.3(2.2) mm long [ratio mucro length/sepel length = 0.09-0.22], with antrorse,  $\pm$  appressed, eglandular hairs 0.3-1.3 mm long and patent (purplish), glandular hairs 0.3-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (10.4)12.2-14.6(20.4) mm long, (3.7)5.1-6(8.4) mm wide, reflexed, rounded, with claw 0.3-0.9 mm long, white or pale pink, usually hairy on the base of the adaxial surface and sometimes on the abaxial surface, with a dense tuft of hairs on the basal margin, with hairs 0.6-1.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments (9.1)10.6-12(15.1) mm long, lanceolate, reddish purple to pink, sparsely pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-1.1(1.6) mm long; anthers (1.8)2.1-2.5(2.6) mm long, blue black. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8.4-13.6 mm long, pale pink to purple. *Fruit* (25)26-28(31.6) mm long, reflexed when immature, discharge of seed-ejection type; mericarps 3.2-4.2 mm long, 1.6-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.5-1 mm long; rostrum 17-22.2 mm long, with a narrowed apex 5.2-6.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.6 mm long; stigmatic remnants (2.6)2.7-3.3 mm long, with 5 glabrous lobes. *Seeds* 2.7-3 mm long, 1.3-1.8 mm wide, smooth, slightly mottled, brown, glabrous. Cotyledons with entire margin. Fig. 144.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 429; Park & Kim 1997: 312).

*Chromosome number.*  $2n = 28$ .

*Phenology.* Collected in flower from June to September.

*Distribution.* This species ranges from Nepal to central China (Sichuan, Xizang and Yunnan) (Fig. 145).

*Habitat.* Meadows, grassy slopes, *Juniperus* L. and *Rhododendron* L. thickets, and edge of *Abies* Mill., *Larix* Mill., *Picea* A. Dietr., *Quercus* L., and *Salix* L. forests; 2900-4800 m.

**Discussion.** *Geranium refractum* is an erect herb with a short vertical rootstock that bears thickened and more or less grouped roots. It has opposite leaves with broadly lanceolate and connate stipules that sometimes have a free apex. The stipules are not as broad as in *G. sinense*. The flowers are nodding, as are the immature fruits that finally become erect. Petals are very narrow and reflexed. They are densely hairy on the basal margins and usually on the base of the adaxial surface and, more rarely, also on the base of the abaxial one. The staminal filaments are sparsely hairy and, occasionally, with long hairs.

Purplish glandular hairs on the inflorescence are usually enough to identify this species unequivocally. In old herbarium specimens, a purplish pigment is sometimes restricted to the apical cell and septa of the glandular hairs. Yeo (1992: 165) suggested that plants from Xizang have whitish flowers, whereas those from Sichuan and Yunnan have pinkish flowers. *Geranium melanandrum* and *G. refractoides* have been differentiated on this basis and by their more obscure stamens and styles. However, these color features are very variable and do not allow for the recognition of different species.

connate (at least at the base), papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1.5-2]; peduncles 14-95 mm long, with patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.3-1.3 mm long; bracteoles 1.9-3.7 mm long, 0.3-0.5 mm wide, linear-lanceolate, whorled; pedicels 18-26 mm long, with patent, eglandular hairs 0.3-0.5 mm long and patent (colourless), glandular hairs 0.4-1.9 mm long. Flowers actinomorphic. *Sepals* 7.2-7.8 mm long, 2.8-3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-1.5 mm long [ratio mucro length/sepal length = 0.05-0.18], with antrorse,  $\pm$  appressed, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.4-1.6 mm long on the abaxial surface, glabrous adaxially. *Petals* 7.3-8.6 mm long, 3.9-5.1 mm wide, reflexed, rounded, with claw 0.5-0.7 mm long, white, glabrous on both surfaces, with a dense tuft of hairs on the basal margin, with hairs 0.6-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 10.1-11.9 mm long, lanceolate, reddish purple, sparsely pilose on the abaxial surface, ciliate on the proximal half, with hairs 2.1-2.9 mm long; anthers 2.4-2.7 mm long, blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 10.2-12.9 mm long, green. *Fruit* 24.4-28.6 mm long, erect, discharge of seed-ejection type; mericarps 2.6-2.7 mm long, 1.5-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.5-0.7 mm long and patent, glandular hairs 0.3-0.9 mm long; rostrum 18-21.9 mm long, with a narrowed apex 5-6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 1-1.2 mm long; stigmatic remnants 1.7-1.8 mm

long, with 5 glabrous lobes. *Seeds* 1.9-2 mm long, 1.5-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 146.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to August.

*Distribution*. This species is endemic to central China (Sichuan and Shaanxi) (Fig. 147).

*Habitat*. Unknown; ca. 700 m.

*Discussion*. *Geranium shensianum* is a representative of the *Refractum Group* because of its connate stipules, nodding flowers, and reflexed petals. The stipules are not as broad as in others species of the group. The leaves of *G. shensianum* have a middle segment rhombic, similar to those of *G. delavayi* or *G. sinense*. The bracteoles are intermediate between those filiform of *G. delavayi* or *G. sinense* and the lanceolate ones of *G. yunnanense*. The glandular indumentum of the inflorescence is similar to that of *G. delavayi*. The staminal filaments have long hairs similar to *G. pogonanthum* and *G. yunnanense*. *Geranium shensianum* also resembles *G. platyanthum* at first sight by the leaf aspect, long hairs of staminal filaments, and cymules partially in aggregates at the top of each branch. However, *G. shensianum* has reflexed and shorter petals, nectaries with hairs, and connate stipules, which are never present in the former.

*Geranium shensianum* is a rare species known from a couple of collections. Its holotype was destroyed in the Berlin herbarium fire and I was not able to locate any duplicate of that collection. The neotype here chosen matches the original description, and was collected in the same region as indicated in the protologue. Additional collections and a focused field study may help to elucidate the variability of this species. It has been recently collected in China (D. Victor, *in litt.*) by gardeners but it is not known where exactly.

**45. *Geranium sinense*** R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 577. 1912. *Geranium platypetalum* Franch., Pl. Delavay.: 111. 1889, [syn. subst.], nom. illeg., non Fisch. & C.A. *Perennial herbs*, 30-89 cm tall. *Rootstock* 6.6-13 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.8(1.7) mm long and, sometimes, patent, glandular hairs 0.3-1.5 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae (4.2)4.8-7.3(12) cm long, 6.5-16.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.80)0.83-0.88(0.90)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic,

(4)5.5-8.4(11.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.09)0.12-0.20(0.23)], (9)11-17(25)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.06)0.12-0.18(0.20)]; petioles up to 38 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.3-0.6(2.3) mm long; stipules 8-20.3

mm long, 2.7-10.7 mm wide, broadly lanceolate, connate (at least at the base), papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (1.2)1.7-2.5(2.7)]; peduncles (17)35-69(82) mm long, with uncinete, eglan-

dular hairs 0.2-0.5 mm long and patent, glandular hairs 0.7-1.7 mm long; bracteoles 2.2-9.2 mm long, 0.2-0.6 mm wide, filiform, whorled; pedicels (5)16-26(29) mm long, with uncinete, eglandular hairs 0.3-0.5 mm long and patent, glandular hairs 0.2-1.6 mm long. Flowers actinomorphic. *Sepals* (4.8)6.8-7.7(9.3) mm long, 2.5-3.6 mm wide, lanceolate, smooth (with a small dark purple zone at the base), not accrescent, nerves 3(5), mucro (0.8)1.3-1.7(2) mm long [ratio mucro length/sepal length = 0.13-0.40], with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.4-1.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.7)7-8.1(9.3) mm long, (5)5.2-6(8.5) mm wide, reflexed, rounded, with claw 0.2-0.9 mm long, blackish red with pale pink base, glabrous on both surfaces, rarely with few hairs on the abaxial surface, sparsely ciliate on the basal margin, with hairs 0.6-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.2)9.7-10.3(11.4) mm long, lanceolate, dark red, glabrous or sparsely pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.4(0.8) mm long; anthers (2.1)2.2-2.3(2.5) mm long, blue black. Nectaries forming a ring around flower, glabrous. *Gynoecium* 6.9-11.3 mm long, dark red. *Fruit* (23.9)24-27(29.5) mm long, reflexed when immature, discharge of seed-ejection type; mericarps

*Discussion.* *Geranium sinense* is a species quite similar to *G. refractum*. Both share a similar habit, nodding flowers and immature fruits, and narrow and reflexed petals. *Geranium sinense* is the only species in the genus with a nectary forming a ring all around the flower. Flower features such as blackish petals, with sparse hairs on the margin, and almost glabrous staminal filaments, further help to identify *G. sinense*. Glandular hairs are finer than in *G. refractum* and are not purple, except for the head. Additionally, the stipules are usually broader than in *G. refractum* and, in contrast, the bracteoles are filiform, not linear-lanceolate as in the latter. The petals are shorter than in *G. refractum*. The inflorescence has 2-flowered cymes on the lower nodes and sometimes an aggregate of cymes toward the apex of each branch. In these aggregates the peduncles are usually short or absent. This feature is shared with *G. delavayi*.

The type of *G. pinetorum* shows all of these characters. Pollen has no deformation and fruit are well developed, which does not support Yeo's view (1992: 169) that *G. pinetorum* could be a hybrid. For these reasons, it is here considered as a synonym of

*G. sinense*. The specimen McLaren 98 (E) lacks glandular hairs on the inflorescence, but otherwise agrees with *G. sinense*.

**46. *Geranium yunnanense* Franch., Pl. Delavay.: 114. 1889. TYPE LOCALITY:** "Yun-nan, ad montis Tsang-chan cacumina, alt. 4000 m.; 19 aug. 1887 (Delavay, n. 2647)". **TYPE:** China. *Discussion*. *Geranium yunnanense* shares a similar habit, broadly lanceolate and connate stipules, nodding flowers, blackish anthers and fruit nodding when immature with *G. refractum*, *G. sinense*, *G. delavayi*, and *G. pogonanthum*. However, it has longer, broader, and not reflexed petals with abundant hairs. Other important characters of this species are its broad bracteoles (sometimes also found in *G. pogonanthum*) and its staminal filaments with abundant long hairs. The indumentum of *G. yunnanense* is essentially eglandular. The specimen *Rock* 6263 (E) has few glandular hairs at the sepal base, but otherwise agrees with *G. yunnanense*.

**The Pylzovianum Group**—The five species here assembled are dwarf alpine plants with long petals and a similar habit and leaf shape. They also share free stipules, 2-flowered cymules and lanceolate staminal filaments. *Geranium pylzovianum* and *G. canopurpureum* share some important features such as a horizontal rootstock consisting of some subglobose tubercles joined by thin and long non-tuberos separations, glabrous nectaries, alternate leaves along the stem, and monochasial inflorescence. In contrast, *G. donianum* and *G. farreri* have

a horizontal rootstock with thickened roots along it, hairy nectaries, opposite leaves, and dichasial inflorescence. *Geranium napuligerum* falls better in the latter subgroup, although it differs in its short vertical rootstock covered by short, thickened and napiform roots and glabrous nectaries.

Stapf (1926) suggested the species here assembled form a "very natural group" but did not support this statement with a relation of shared characters. In contrast Yeo (2002a) separated them in three groups ("Farrieri Group", "Stapfianum Group" and *Pylzovianum Group*).

**47. *Geranium canopurpureum* Yeo**, Edinburgh J. Bot. 49(2): 138, 139 fig. 3. 1992. TYPE LOCALITY: "Yunnan, 193?, Yü 7742 (holo. A)". TYPE: China. Sichuan, Muli Zhangzu Zhizhixian, between Guma Dian and Shaoxiang Liang, 28°16'N, 101°21'E, 8 Aug. 1937, *T.T. Yü* 7742 (holotype, A-00263536!).

*Perennial herbs*, 7-9 cm tall. *Rootstock* ± horizontal, tuberculate, with tubercles subglobose, 3.7-4 mm long, 2.9-3.5 mm wide, with non-tuberos separations 4-16 mm long, 0.6-1 mm wide, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retorse to appressed, eglandular hairs 0.2-0.3 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves alternate (usually 1) and upper opposite; leaf laminas 0.7-1.4 cm long, 1.2-1.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.73-0.80], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on the adaxial surface and ± sericeous abaxially; segments 5, in 1 plane, middle segment obtriangular, 1.2-1.5 mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.27], 1-3-lobed in distal half [ratio secondary sinus length/

middle segment length = 0.19-0.26]; petioles up to 5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse to appressed, eglandular hairs 0.2-0.4 mm long; stipules 1.8-2.8 mm long, 0.7-0.9 mm wide, lanceolate, free, papery, dark purplish, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a monocha-

sial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.7-3]; peduncles 29-47 mm long, with retrorse to appressed, eglandular hairs 0.2-0.3 mm long; bracteoles 3.9-5.2 mm long, 0.5-0.6 mm wide, lanceolate, whorled; pedicels 20-34 mm long, with retrorse to appressed, eglandular hairs 0.2-0.3 mm long. Flowers actinomorphic. *Sepals* 5.3-6.3

Fig. 153. Distribution of *Geranium canopurpureum*.

J. L. Castillo, 2007

Fig. 152 *Geranium canopurpureum*. a. Habit. b, c. Leaves. d. Bracteoles. e. Flower. f. Flower without petals and sepals. g. Sepal. h. Petal. i. Staminal filament. (Based on: Yü 7742, GH).

mm long, 1.8-2.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-0.8 mm long [ratio mucro length/sepal length = 0.11-0.15], with antrorse to patent, eglandular hairs 0.1-0.4 mm long on the abaxial surface, glabrous adaxially. *Petals* 8.4-11.9 mm long, 4.5-5 mm wide, erect-patent, rounded, without claw, reddish purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.8-5.9 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.8 mm long; anthers 1.1-1.3 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.9-6.8 mm long, dark purple. *Fruit* unknown. *Seeds* unknown. Cotyledons not studied. Fig. 152.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in August.

*Distribution*. This species is endemic to Sichuan, in south-central China (Fig. 153).

*Habitat*. Forest edges; ca. 3500 m.

*Discussion*. At first sight, *Geranium canopurpureum* could be considered as a reduced form of *G. pylzowianum*. Both species share a similar rootstock and inflorescence structure. However, *G. canopurpureum* has leaves

that are not as divided as *G. pylzowianum* and ± sericeous on the abaxial surface, petals that are attenuate (without a claw) and without hairs on the adaxial surface, and stipules and bracteoles that are dark purplish. In small specimens of *G. pylzowianum*, petal length is not reduced, and these other characters of *G. canopurpureum* are not present, which also supports the independence of the latter.

This species is known only by the type specimen, which lacks fruits. In *G. canopurpureum* glandular hairs has not been found but the scarcity of the sampling prevents against any definitive conclusion. The protologue incorrectly indicated that the holotype was from Yunnan. The correct information, based on records at PE, is that the collection was made in Muli, Sichuan (H.N. Qin, *pers. comm.*).

**Discussion.** *Geranium donianum* is a small plant with a horizontal rootstock that bears thickened roots distributed along it. It has opposite leaves and free stipules. Occasionally, some cymules arising directly from the rootstock have been observed. The indumentum of the whole plant is usually eglandular. The long petals are hairy on the base of the adaxial surface. They are usually emarginate at the apex and without a distinct claw. The nectaries are dorsally glabrous, with a tuft of hairs at the top; rarely, they appear almost glabrous. The specimen *MacArthur 2943* (US) has scattered glandular hairs on the stem and petioles, but otherwise it falls within the variability of the species.

*Geranium stapfianum* is considered by Stapf (1926) and Yeo (1992: 162) to be a different species endemic to Sichuan and Yunnan, *G. donianum* thus being a Himalayan plant. In order to support such a distinction, a more robust rootstock and habit are attributed to western specimens of *G. donianum*. However, a great variability in these features has been observed throughout the whole area of *G. donianum*, and this does not support such a division. The rootstock could rarely have some thickened areas that are not clearly differentiated, which should not be mistaken with the tubercles of *Geranium pylzowianum*. Additionally, *G. pylzowianum* has glandular indumentum, glabrous nectaries, and usually some alternate leaves and entire petal apex.

**49. *Geranium farreri*** Stapf, Bot. Mag. 151, tab. 9092. 1926. TYPE LOCALITY: "The second form [F. 170] is the plant figured here... **Perennial herbs**, 9-16(19) cm tall. **Rootstock** 3.7-4.3(6.7) mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with sparse, retrorse, not appressed, eglandular hairs 0.2-0.3 mm long. **Basal leaves** in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminae (1.3)1.5-1.9 cm long, 1.9-3.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.74-0.82(0.84)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (1.8)2-2.5(2.9) mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.21], 3-5-lobed in distal half [ratio secondary sinus length/middle segment length = (0.23)0.25-0.28(0.33)]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.4 mm long; stipules 4.6-7.4 mm long, 0.9-2.9 mm wide, lanceolate, free, papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. **Inflorescence** a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.3)1.4-2.1(2.7)]; peduncles (32)36-54(69) mm long, with retrorse, not appressed, eglandular hairs 0.3-0.5 mm long; bracteoles 3.5-5.7 mm long, 0.7-1.5 mm wide, lanceolate, whorled; pedicels (24)30-35(44) mm long, with retrorse, not appressed, eglandular hairs 0.2-0.5 mm long. Flowers actinomorphic. **Sepals** (7.9)8-8.9(9.2) mm long, 3.2-4.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.6(0.7) mm long [ratio

mucro length/sepal length = 0.05-0.09], with antrorse,  $\pm$  appressed, eglandular hairs 0.4-0.6 mm long on the abaxial surface, almost glabrous adaxially. *Petals* 14.6-16(16.7) mm long, (9.7)10.1-12.6(12.9) mm wide, erect-patent, rounded (rarely retuse), with claw 2.3-6.1 mm long, pale pink, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the

basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 9-11.8 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.4 mm long; anthers (2.1)2.2-2.4(2.6) mm long, dull purple to blackish. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8-13.3 mm long,

pink. *Fruit* ca. 23 mm long, erect, discharge of seed-ejection type; mericarps 3.5-4 mm long, 1.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown; stigmatic remnants with 5 glabrous lobes. *Seeds* 2.8-3 mm long, 1.5 mm wide. Cotyledons not studied. Fig. 156.

*Pollen*. *Geranium*-type (Park & Kim 1997: 314).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to August.

*Distribution*. This species is endemic to Gansu, in central China (Fig. 157).

*Habitat*. Bluffs and limestone outcroppings; 4300-4600 m.

*Additional specimens examined*. **China**. GANSU: Schr Hsia, in latere N montis Min-shan, 34°26'N, 103°58'E, 24 July 1930, *Hummel* 4415 (S); Tao river basin, N of Chabaku pass, 35°40'N, 103°36'E, Aug. 1925, *Rock* 13184 (E, GH, NY, US). **Unknown origin**. Farrer expedition to Burma 1919 or Kansu / Tibet 1914-15, July, *Farrer Exped.* s.n. (E).

*Discussion*. *Geranium farreri* is quite similar to *G. donianum*, although it is well characterized by its petals: they have a rounded or retuse apex and a distinct claw. Fruit features are poorly known because of the scarcity of available material. The geographical separation of *G. farreri* also supports its independence.

*Discussion.* At first sight, *G. napuligerum* resembles *G. donianum* in habit, leaf shape, and inflorescence structure. *Geranium napuligerum*, however, is well characterized by its short, thickened, and napiform roots. The short rootstock is usually covered by the roots. In this feature it resembles *G. dahuricum*, but the latter is a more robust plant that has roots in a fascicle and they are appreciably longer. Glandular hairs also support the distinctiveness of *G. napuligerum* against *G. donianum*. They are usually restricted to stipules, sepal and bracteole bases, mericarps, and the abaxial surface of leaves. More rarely, there are glandular hairs on the stem, peduncles, and pedicels.

*Geranium napuligerum* is an endemic from Yunnan and Sichuan. Knuth (1912: 143) recorded it in Korea on the basis of the specimen *Faurie* 1760, which is *Geranium dahuricum*.

**Discussion.** *Geranium pylzowianum* is a small plant with a horizontal rootstock consisting of some subglobose tubercles joined by thin and long non-tuberous separations. It usually has 1(or 2) alternate leaves along the stem and some opposite at the inflorescence. In some specimens, cauline leaves are all opposite, and then the inflorescence is branched from the basal node monochasially. Occasionally some cymules arising directly from the rootstock have been observed. The indumentum is predominantly eglandular, but scattered glandular hairs usually appear on the stem base, petioles, and peduncles. The petals are hairy on the basal third

Fig. 161. Distribution of *Geranium pylzowianum*.

of the adaxial surface and have a rounded or slightly emarginate apex and a short claw.

Yeo (1992) recognized *Geranium orientalitibeticum* by its broad leaf blade segments, petals with a paler base, and longer stigmatic remnants. These features are, however, included in the variability of *G. pylzowianum*.

*Geranium pylzowianum* has sometimes been confused with *G. donianum* and *G. farreri*, which are quite similar in appearance but with rootstock without tubers and always opposite leaves. Additionally, in *G. pylzowianum* there are usually glandular hairs on the stem base, petiole, or inflorescence.

**The Palustre Group**—Members of this group are erect perennial herbs with an essentially eglandular indumentum, usually with connate stipules and sometimes with fasciculate roots, moderately divided leaves, lanceolate stamens, and large petals that are hairy usually on the base of the adaxial surface. The cymules are 2-flowered and usually arranged in a monochasial inflorescence.

Yeo (2002a: 101) assembled the *Palustre Group* with *G. palustre*, *G. wlassowianum*, *G. donianum*, *G. shikokianum*, and *G. koreanum*. He stated that is very closely related to the *Krameri Group* and that it is mainly distinguished from the latter by the absence of hairs over an extensive area of the adaxial surface (except in *G. koreanum*) of the petal. They share a predominantly eglandular indumentum and stipules at least partially connate, which suggest their close relation. *Geranium donianum* is transferred here to the *Pylzowianum Group* because of its close similarity with *G. farreri*.

*Perennial herbs*, 34-87 cm tall. *Rootstock* 8-15 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed or patent, eglandular hairs 0.1-1.8 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminas (6.3)7.6-9.2(10) cm long, 7.7-13.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.65)0.72-0.79(0.80)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (10.7)16-19(26.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.21)0.25-0.30(0.40)], (8)9-13(14)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.09)0.13-0.15(0.20)]; petioles up to 21 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed or patent, eglandular hairs 0.2-1.7 mm long; stipules 5.9-15.6 mm long, 2.9-10.9 mm wide, broadly ovate, usually connate, papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.4)2-2.6(3)]; peduncles (25)39-87(103) mm long, with retrorse, appressed or patent, eglandular hairs 0.1-0.8 mm long; bracteoles 1.8-9.4 mm long, 0.5-2 mm wide, lanceolate, whorled; pedicels (14)20-33(36) mm long, with retrorse, appressed or patent, eglandular hairs 0.1-0.7 mm long. Flowers actinomorphic. *Sepals* (7.4)7.7-10(11.5) mm long, 2.5-4.6 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (1.3)1.7-2.7(3.9) mm long [ratio mucro length/sepal length = 0.15-0.40], with antrorse, ± appressed, eglandular hairs 0.1-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (11.9)14.7-16.5(21.1) mm long, (6.1)8.1-10.1(13)

mm wide, erect-patent, rounded, without claw, bright pink, hairy on the basal 1/3 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.5-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments (6.4)8.8-10.5(11) mm long, lanceolate, pink, almost glabrous, with

scattered hairs 0.1-0.5 mm long on the abaxial surface and margin; anthers (1.9)2.1-2.8(2.9) mm long, blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 7.5-13.3 mm long, dull red. *Fruit* (26.7)27.1-30.1(39.9) mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.7 mm long, 2-2.4 mm

wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.4 mm long and, rarely, patent glandular hairs 0.6-0.8 mm long (mainly at the top of the mericarp); rostrum 17.4-23.8 mm long, with a narrowed apex 2.3-5.1 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and, rarely, patent, glandular hairs 0.5-0.6 mm long; stigmatic remnants (4.8)5-6.3(8.8) mm long, with 5 glabrous lobes. *Seeds* 2.6-3 mm long, 1.3-2.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 162.

*Pollen*. *Geranium*-type (Lu & al. 1996: 320; Park & Kim 1997: 314).

*Chromosome number*.  $2n = 28+2B$ .

*Phenology*. Collected in flower from June to November.

*Distribution*. This species ranges from eastern China (Anhui and Shandong) to South Korea (Fig. 163).

*Habitat*. Roadsides and open fields; 550-1800 m.

*Additional specimens examined*. **China**.

**Discussion.** *Geranium koreanum* is an erect herb quite similar to *G. shikokianum*. Both species share a  $\pm$  vertical rootstock with thickened roots along it (not fasciculate) and broad and connate stipules. The stipules of *G. koreanum* are noticeably broad, resembling those of *G. wallichianum*, a species of Central Himalayas that has been erroneously recorded in Korea (Knuth 1912: 195). The latter, however, has blackish filaments, anthers, and stigma, and broad bracteoles, not found in *G. koreanum*. The petals of *G. koreanum* are hairy on the basal third of the adaxial surface, while in *G. shikokianum* they are hairy only on the base. The latter has more deeply primary and secondary leaf sinus. The connate stipules of *G. maximowiczii* and *G. wlassovianum* are not so broad and are sometimes not fused at the apex.

*Geranium hattae* Nakai, Bot. Mag. (Tokyo) 26: 263. 1912, ["Hattai"]. *Geranium wlassovianum* var. *hattae* (Nakai) Z.H. Lu, Bull. Bot. Res., Harbin 14: 360. 1994. TYPE LOCALITY: "Hab. Korea sept. Sandö 8. VII. 1909. (K. Hatta)". TYPE: North Korea. Sando, 40°39'N, 128°29'E, 8 July 1909, *K. Hatta s.n.* (lectotype, here designated, TI!).

**Perennial herbs**, 29-75 cm tall. **Rootstock** 5-12.7 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with a fascicle of long and thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent (rarely retrorse, appressed), eglandular hairs 0.5-1.6 mm long. **Basal leaves** in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminas (3.1)5.8-7.2(9.7) cm long, 4.6-11.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.59)0.66-0.78(0.84)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (8.3)11.8-16(19) mm wide at the base [ratio segment width at the base/middle segment length = (0.19)0.25-0.33(0.43)], (4)6-7(8)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.11)0.15-0.18(0.25)]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with usually patent, eglandular hairs 0.5-1.6 mm long; stipules 2.9-7 mm long, 1.2-3.5 mm wide, lanceolate, free or connate (at least at the base), papery, brown, with scattered, eglandular hairs on

both surfaces and on the margin. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.2)2-3.2(8.4)]; peduncles (35)54-101(146) mm long, with patent, eglandular hairs 0.2-1.6 mm long; bracteoles 1.7-6.7 mm long, 0.3-1 mm wide, lanceolate, whorled; pedicels (15.5)26-41(67) mm long, with usually retrorse,  $\pm$  appressed, eglandular hairs 0.1-1.1 mm long. Flowers actinomorphic. **Sepals** (5.6)6.6-7.8(8) mm long, 1.8-3.6 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro (0.9)1.2-2.1(3.2) mm long [ratio mucro length/sepal length = 0.10-0.40], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long and  $\pm$  patent, eglandular hairs 0.3-2.2 mm long on the abaxial surface, glabrous adaxially. **Petals** (9.1)11.4-14.1(15.2) mm long, (3.7)5.2-7.1(9.5) mm wide, erect-patent, rounded, without claw, deep purple magenta, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.4-0.9 mm long. **Stamens** 10, both whorls bearing anthers; filaments (6.1)6.8-8.2(9.6) mm long, lanceolate, pink, sparsely pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.6(1.1) mm long; anthers (1.1)1.3-1.8(1.9) mm long, blue. Nectaries 5, hemispheric, glabrous. **Gynoecium** 5.8-9.8 mm long, purple. **Fruit** (22)23-28(33) mm long, erect, discharge of seed-ejection type; mericarps 2.8-4.2 mm long, 1.5-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-0.7 mm long and, usually, patent, glandular hairs 0.5-1 mm long (mainly at the top of the mericarp); rostrum 13.9-24.3 mm long, with a narrowed apex 1.9-4.5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and, usually, patent, glandular hairs 0.5-0.7 mm long; stigmatic remnants (3.3)3.6-4.6(5.3) mm long, with 5 glabrous lobes. **Seeds** 2.2-2.6 mm long, 1.2-1.7 mm wide, finely reticulate, uniformly colored, brown, gla-

brous. Cotyledons with entire margin. Fig. 164.

**Pollen.** *Geranium*-type (Lu & al. 1996: 320).

**Chromosome number.**  $2n = 28$ .

**Phenology.** Collected in flower from May to September.

**Distribution.** This species ranges from eastern Siberia (Amur,

Khabarovsk and Primorye) and Korea to northeastern China (Hebei, Heilongjiang and Nei Mongol) (Fig. 165).

**Habitat.** Meadows, shrubby formations and mixed and conifers forest edges; 0-1800 m.

**Additional specimens examined.** **China.** **HEBEI:** Hsiao-wu-tai-shan, Yang-kia-

p'ing, Tung-lin, 40°0'N, 115°30'E, 6 Sep. 1921, *Smith 1120* (UPS). **HEILONGJIANG:** Heilongjiang, 47°45'N, 128°0'E, 1959, *Mu Dan Jiang Exped. 117* (PE). **NEI MONGOL:** ciudad Chifeng, distrito Ningwu, 42°16'N, 118°57'E, 1 Sep. 1997, *Liu Tiezhi 237* (MO); ciudad Hulun Bei Er, municipio E'erguna, 48°57'N, 117°46'E, 2 Aug. 1951, *Wang Zhan 1650* (MO). **North Korea.** **RYANGGANG:** prov. Cham-gion, flum. Jumin-yan, 41°12'N, 128°12'E, 10 June 1897, *Komarov 996* (Fl, P, W). **Russia.** **AMUR:** prov. Amuriensis, vallis Mutnaja non procul statione Paschkova, 48°52'N, 130°39'E, 2 July 1895, *Komarov 996b* (GH, TI); Amurskaia obl., Amur-Zejsoke plateau, 16 km on the route Zaja-Zolotaja gora, 54°16'N, 126°37'E, 27 Aug. 1957, *Nepli s.n.* (C). **KHABAROVSK:** prov. Amur in monte Henzien prope stationen ferream Korfowskaja, 40 km procul ab oppidum Chabarowsk, 48°13'N, 135°4'E, 3 Aug. 1913, *Enander s.n.* (S); est. Jeitsir, km. 19 de la carretera de Vladivostok, 48°17'N, 135°5'E, 24 July 2004, *Tsirenova s.n.* (VLA); pueblo Petropavlovka, 48°41'N, 135°32'E, 17 June 1969, *Novichkova s.n.* (VLA); pueblo Vyatskoye del Amur, distrito Nanayskiy, 48°44'N, 135°43'E, 29 June 1972, *Baitsova s.n.* (VLA); pueblo Vyatskoye, 48°44'N, 135°43'E, 22 June 1973, *Bren s.n.* (VLA). **PRIMORYE:** Vladivostok, 43°7'N, 131°55'E, May 1919, *Topping 2299* (US); Vladivostok, 43°7'N, 131°55'E, May 1919, *Topping 2377* (US); Vladivostok, 43°7'N, 131°55'E, May 1919, *Topping 2503* (US). **South Korea.** **Gyeonggi:** Jinsen, 37°27'N, 126°43'E, 11 Nov. 1900, *Uchiyama s.n.* (LD).

**Discussion.** *Geranium maximowiczii* is a species quite similar and sometimes difficult to differentiate from *G. wlassovianum*. Both share a short vertical rootstock with a fascicle of thickened roots, shallowly divided leaves,

Fig. 164. *Geranium maximowiczii*. a, b. Habit. c, d. Stipules. e. Leaf indumentum on adaxial side. f. Leaf indumentum on abaxial side. g. Bracteoles. h. Flower. i. Liu 237*, MO; h-k, *Hatta s.n.*, 8 July 1909, TI).

Fig. 165. Distribution of *Geranium maximowiczii*.

paler on the abaxial surface, and petals with hairs only on the base. Sepals, petals, and stigmatic remnants are shorter in *G. maximowiczii*, although with some overlap. Additionally, in *G. maximowiczii*, the anthers, gynoecium, fruit, and staminal filaments are shorter. The indumentum of staminal filaments varies in density but is never as dense as in *G. wlassovianum*. Hairs on the stem and inflorescence are a bit longer and, usually appressed.

*Perennial herbs*, 30-78 cm tall. *Rootstock* 10-15 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-1.6 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminas (4.8)5.7-9.4(10.8) cm long, 5.9-12.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.71)0.74-0.81(0.93)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (6.1)9-14.8(17.9) mm wide at the base [ratio segment width at the base/middle segment length = (0.13)0.18-0.23(0.31)], (6)9-14(17)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.20)0.24-0.26(0.29)]; petioles up to 30 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.6-1.6 mm long; stipules 4.8-13.4 mm long, 1.3-4.5 mm wide, lanceolate, connate (at least at the base), papery, brown, subglabrous on both surfaces, ciliate on the margin. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.5)2.7-3.2(3.6)]; peduncles (27)48-89(179) mm long, with patent to retrorse-appressed, eglandular hairs 0.2-1.2 mm long; bracteoles 4.3-14.7 mm long, 0.6-1.8 mm wide, lanceolate, whorled; pedicels 27-40(49) mm long, with retrorse, ± appressed, eglandular hairs 0.2-1.3 mm long. Flowers actinomorphic. *Sepals* (7)7.6-8.6(8.9) mm long, 2.8-3.7 mm wide, lanceolate, with thickened nerves, not accres-

cent, nerves 5, mucro (1.6)1.8-2.2(2.8) mm long [ratio mucro length/sepal length = 0.21-0.37], with antrorse, appressed, eglandular hairs 0.2-0.6 mm long on the abaxial surface (mainly on the nerves), glabrous adaxially. *Petals* (13.8)14.4-16.5(17.6) mm long, (6.3)8.2-8.8(9.7) mm wide, erect-patent, rounded, without claw, purple, hairy on the base of the adaxial sur-

face, glabrous abaxially, ciliate on the basal margin, with hairs 0.5-1.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.2)7-8.2(8.5) mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.4 mm long; anthers (1.2)2-2.1 mm long, blue or cream. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5.6-7.9 mm long,

purple. *Fruit* (25)26-28(29) mm long, erect, discharge of seed-ejection type; mericarps 3.1-3.6 mm long, 1.4-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.7 mm long and patent, glandular hairs 0.6-0.8 mm long (mainly at the top of the mericarp); rostrum 16-20 mm long, with a narrowed apex 2.3-3.4 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 2.7-4.1 mm long, with 5 glabrous lobes. *Seeds* 2.1-2.7 mm long, 1.3-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 166, 167.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 431; Park & Kim 1997: 314; Stafford & Blackmore 1991: 72).

*Chromosome number.*  $2n = 28, 56$ .

*Phenology.* Collected in flower from June to September.

*Distribution.* This species ranges from northern and central Europe to southern Caucasus (Fig. 168).

*Habitat.* Roadsides, moist meadows, grassy marshes, streams and shrubby formations; 100-2200 m.

*Representative specimens examined. Armenia.* GEGHARKUNIK: Nor-Bajazet, in jugo Karni-jarych, 40°21'N, 45°7'E, 15 Aug. 1928, Zedelmejer & Gejdeman s.n. (LE). **Discussion.** *Geranium palustre* is well characterized by its sepals with five thickened nerves, that have short, antrorse-appressed, eglandular hairs mainly on nerves. The indumentum of stem, petioles, and peduncles

consists of spread, eglandular hairs, while on pedicels these hairs are usually retrorse-appressed ones. Only on the apex of the mericarps have some glandular hairs been found. *Geranium palustre* is an erect herb with a thick and long, horizontal rootstock that has thickened roots along it. It has glabrous nectaries, opposite leaves, and connate stipules for at least a part of their length.

*Geranium palustre* resembles *G. wlassovianum* in general appearance. The latter has, however, a fascicle of long and thickened roots on a short and vertical rootstock, hairy nectaries, and longer peduncles, sepals, petals, stamens, and fruits, although with some overlap.

*Perennial herbs*, 30-60(80) cm tall. *Rootstock* 6.1-9.3 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.6-1.2 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminas (2.6)4.6-7.4 cm long, (3.1)5.8-10.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.74)0.79-0.84(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (3.6)8.5-10.5(12.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.15)0.18-0.22(0.30)], (7)9-13(17)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.17)0.21-0.25(0.31)]; petioles up to 17 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed or patent, eglandular hairs 0.4-1.3 mm long; stipules 4.1-13 mm long, 3.6-9.4 mm wide,

broadly ovate, connate, papery, brown, glabrous on both surfaces, sometimes with some short ciliae. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.3)1.9-2.5(3.1)]; peduncles (27)42-85(115) mm long, with retrorse, appressed or patent, eglandular hairs 0.2-1 mm long; bracteoles 3.2-9.3 mm long, 1-2.9 mm wide, lanceolate, whorled; pedicels (14)20-33(44) mm long, with retrorse, appressed or patent, eglandular hairs 0.2-1 mm long. Flowers actinomorphic. *Sepals* (6.1)7.4-8.6(9.8) mm long, 2.5-3.8 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (1.1)1.5-2.4(3.2) mm long [ratio mucro length/sepal length = 0.14-0.37], with patent, eglandular hairs 0.4-1.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (11.9)13-16.6(19.3) mm long, 6.2-11(12.6) mm wide, erect-patent, rounded (rarely retuse or lobed), without claw, purple, glabrous on both surfaces, rarely with some hairs on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.6-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.4)6.7-7.9(9) mm long, lanceolate, white, with scattered hairs 0.1-0.4 mm long on abaxial surface and margin; anthers (1.7)1.8-2.3(2.4) mm long, purple. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6.1-9.5 mm long, unknown color. *Fruit* 26.2-32(33.6) mm long, erect, discharge of seed-ejection type; mericarps 3.6-4.8 mm long, 2-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-0.8 mm long and, usually, patent glandular hairs 0.5-1 mm long (mainly at the top of the mericarp); rostrum 17-21.8 mm long, with a narrowed apex 1.4-3.9 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and, rarely, patent glandular hairs 0.5-0.9 mm long; stigmatic remnants

(4)4.5-5.1 mm long, with 5 glabrous lobes. *Seeds* 2.8-2.9 mm long, 1.4-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 169.

*Pollen*. *Geranium*-type (Park & Kim 1997: 312).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from June to September.

**Discussion.** *Geranium shikokianum* is an erect perennial herb, easily identified by its broadly ovate, connate stipules, and glabrous petals, except for some cilia at the base. The indumentum consists of eglandular hairs, scattered at the stem base and more abundant toward the inflorescence. The hairs are retrorse or spreading. The sepal indumentum is composed of both appressed hairs on the abaxial surface and longer, spreading hairs on the nerves. Finally, there are some glandular hairs at the apex of the mericarp and, sometimes, at the base of the fruit rostrum. The petals are usually glabrous on the adaxial surface, but with cilia on the basal margins. In some rare cases a few hairs occur on the adaxial petal base. The petal apex is usually rounded, although in some cases, it is retuse with a 2- or 3-lobed apex. The inflorescence has monochasial branches, with a cymule and a pair of leaves arising from each node. Each branch usually ends in two cymules, one longer than the other. The connate stipules are broadly ovate and sometimes with a slightly cordate base. Among the specimens examined, this character appears to be constant, i.e., present at all nodes on all individuals.

*Geranium shikokianum* is quite similar to *G. koreanum*. It can be distinguished from the latter by its more deeply divided leaves with narrower segments and its petals nearly glabrous on the adaxial surface.

I have not been able to find type material of *G. shikokianum* at either TI or K, where types of Matsumura should be kept, and thus a neotype, collected at the original locality, is proposed. *Faurie 1758*, on which *G. shikokianum* var. *quelpaertense* is

Fig. 170. Distribution of *Geranium shikokianum*.

based, is heterogeneous. One of the duplicates of this number at E is *G. thunbergii* and is explicitly excluded as lectotype material of this name.

**56. *Geranium wlassovianum*** Fisch. ex Link, Enum. Hort. Berol. Alt. 2: 197. 1822. TYPE LOCALITY: "Hab. in Sibiria". TYPE: Russia. Chita, Ingoda, 51°42'N 115°50'E, *F.E. Fischer s.n.* (lectotype, designated by Knuth 1912: 179, B destroyed). Russia. Chita, Dahuria, 50°58'N, 112°57'E, *O.F. Vlassow s.n.* (neotype, designated by Tsyrenova 1985a: 1640, LE-Fischer D16!).

*Geranium wlassovianum* DC., Mém. Soc. Phys. Genève 1: 441. 1823. TYPE LOCALITY: "La plante, que je désigne ici, est provenue de graines envoyées des jardins d'Allemagne sous ce nom, que je conserve dans l'idée qu'elle a peut-être été décrite dans quel-qu'ouvrage à moi inconnu: ce nom qui fait allusion à celui de Vlassov, botaniste Russe, parait indiquer que l'espèce est originaire de l'empire Russe". TYPE: Cultivated from seeds from Germany gardens, probably from Russia, "h. Genev.", 6 June 1821, *unknown collector* (lectotype, here designated, G-DC-215447!).

Prov., Jeju Island, Jeju City, Ara-I-dong (33°25'51.62"N, 126°33'28.65"E), August 26, 2004, B.-J. Woo & S.-J. Park 2040816 (holotype, YNUH)". TYPE: South Korea. Jeju, Jeju Island, Jeju City, Ara-I-dong, 33°25'N, 126°33'E, 26 Aug. 2004, *B.J. Woo & S.J. Park 2040816* (holotype, YNUH).

*Perennial herbs*, 25-86 cm tall. *Rootstock* 7-16.8 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with a fascicle of long and thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent (rarely retrorse, appressed), eglandular hairs 0.3-1.1 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminas (3.7)6-6.8(8.1) cm long, 4.7-9.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.70)0.73-0.81(0.84)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (6)8-12.6(19.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.13)0.17-0.25(0.37)], 7-9(10)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.14)0.21-0.26(0.29)]; petioles up to 24 cm long, without abscission zone, terete, not swollen, not deflexed in age, with usually patent, eglandular hairs 0.2-1.1 mm long; stipules 3.1-10 mm long, 1.9-4.7 mm wide, lanceolate, free or connate (at least at the base), papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.5)2-3.4(4.6)]; peduncles (43)65-123(164) mm long, with ± patent, eglandular hairs 0.2-1 mm long; bracteoles 3.6-9.5 mm long, 0.5-1.3 mm wide, lanceolate, whorled; pedicels (20)29-39(62) mm long, with patent or retrorse, ± appressed, eglandular hairs 0.2-0.8 mm long. Flowers actinomorphic. *Sepals* (7.9)8.9-10.3(11.2) mm long, 2.9-4.9 mm wide, lanceo-

late, with thickened nerves, not accrescent, nerves 5, mucro (1.1)1.6-2.5(3.9) mm long [ratio mucro length/sepal length = 0.12-0.38], with antrorse, ± appressed, eglandular hairs 0.1-0.3 mm long and ± patent, eglandular hairs 0.2-1.4 mm long on the abaxial surface, glabrous adaxially. *Petals* (15.5)16.1-19.5(23) mm long, (5.5)8.3-10.1(13.5) mm wide, erect-patent, rounded, without claw, deep magenta-purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-1.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments (8.5)9.5-11.2(12.1) mm long, lanceolate, pink, densely pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.6-1.5 mm long; anthers (1.6)2.1-2.5(2.6) mm long, blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8.9-13.1 mm long, deep red or pink. *Fruit* (30.4)32-35(37.7) mm long, erect, discharge of seed-ejection type; mericarps 2.9-4.3 mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.3-1.1 mm long and, usually, patent glandular hairs 0.6-1 mm long (mainly at the top of the mericarp); rostrum 20.7-25.9 mm long, with a narrowed apex (3)3.4-4.8(5.2) mm long, not twisted, with ± patent, eglandular hairs 0.2-0.3 mm long and, usually, patent, glandular hairs 0.5-0.9 mm long; stigmatic remnants 5-6.9 mm long, with 5 glabrous lobes. *Seeds* 2-2.5 mm long, 1.4-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 171.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 431; Lu & al. 1996: 320; Park & Kim 1997: 312).

*Chromosome number*.  $2n = 28, 56$ .

*Phenology*. Collected in flower from June to October.

*Distribution*. This species ranges through Mongolia, eastern Siberia (Amur, Buryatiya, Chita, Irkutsk and

Primorye) and eastern China (Hebei, Heilongjiang, Henan, Jilin, Nei Mongol, Shandong and Shanxi) (Fig. 172).

**Habitat.** Roadsides, moist meadows, lake shores, marshes, riverbanks and edge of *Betula* L. and *Salix* L. forests; 500-2300 m.

*Representative specimens examined.*

**Discussion.** *Geranium wlassovianum* is an erect perennial herb, easily identified by its short vertical rootstock with a fascicle of long and thickened roots, its shallowly divided leaves and its long petals with hairs only on the base. The indumentum consists of eglandular hairs, spread or, more rarely, retrorse. At the apex of the mericarp and at the base of the fruit rostrum

there are some glandular hairs. The sepals have thickened nerves and an indumentum that consists of short appressed hairs and long and spread hairs. The petals are hairy on the base of the adaxial surface and ciliate on the basal margin. The inflorescence is monochasially arranged, with a cymule and a pair of leaves arising from each node. The peduncle of the cymules is noticeably long toward the base of the inflorescence. The connate stipules of *G. wlassovianum* are more similar to those of *G. koreanum* or *G. shikokianum*, although not as wide. They are usually connate for at least part of their length. In some cases they appear free, at least at some nodes of the plant.

*Geranium wlassovianum* and *G. maximowiczii* share shallowly divided leaves, paler on the abaxial surface. Both species are difficult to differentiate, and the main characters are referred to in the key. Additionally, in *G. wlassovianum*, the anthers, gynoeceum, fruit, and staminal filaments are longer (and with a dense tuft of hairs). Hairs on the stem and inflorescence are also longer and usually patent.

Knuth (1912: 179) typified *G. wlassovianum* on a Fischer's specimen from B herbarium now destroyed. Tsyrenova (1985a) proposed the lectotype from Fischer's herbarium at LE but did not quote Knuth's designation. Thus, I consider that, in fact, she was designated a neotype.

De Candolle (1823: 441) published his *G. wlassovianum* which should be considered heterotypic and perhaps a homonym of *G. wlassovianum*. He indicated that: "La plante, que je désigne ici, est provenue de graines envoyées des jardins d'Allemagne sous ce nom, que je conserve dans l'idée qu'elle a peut-être été décrite dans quel-qu'ouvrage à moi inconnu: ce nom qui fait allusion à celui de Vlassov, botaniste Russe, paroît indiquer que l'espèce est originaire de l'empire Russe". Thus, it seems that Link (1822) and De Candolle (1823) published this species almost simultaneously yet independently.

**The *Krameri* Group**—Members of this group are erect perennial herbs with an essentially eglandular indumentum, usually with connate stipules and fasciculate roots, deeply divided and opposite leaves, lanceolate stamens, and large petals that are hairy on the adaxial surface. The cymules are predominantly 2-flowered and usually arranged in a monochasial inflorescence.

*Perennial herbs*, 22-48(72) cm tall. *Rootstock* 4-8 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with a fascicle of long and thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.3-1 mm long. *Basal leaves* in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminae (3.4)3.8-5.6(6.2) cm long, 3.9-7.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.83)0.86-0.95], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (1.6)2.9-4.8(5.7) mm wide at the base [ratio segment width at the base/middle segment length = (0.04)0.08-0.13(0.15)], 4-7(10)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.23)0.31-0.36(0.46)]; petioles up to 24 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-1 mm long; stipules 3-6.5 mm long, 0.9-3.2 mm wide, lanceolate, connate (at least at the base), papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.8)2-3.1(4.2)]; peduncles (22)40-91(100) mm long, with retrorse, appressed, eglandular hairs 0.3-0.9 mm long; bracteoles

2.6-6.9 mm long, 0.4-1.1 mm wide, lanceolate, whorled; pedicels (13)21-33(44) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* (5.4)5.8-7.1(9) mm long, 1.6-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro (0.9)1-1.5(2) mm long [ratio mucro length/sepal length = 0.13-0.28], with antrorse,  $\pm$  appressed, eglandular hairs 0.3-1.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (7.9)8.7-13.2(14) mm long, (3.8)4.2-7.9(8.8) mm wide, erect-patent, rounded, without claw, light pink, hairy on the basal 1/3-1/2 of their adaxial surface (rarely up to the apex) and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.4-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (3.8)5-7.1(7.5) mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.8 mm long; anthers (1.4)1.5-1.7(2) mm long, blue. Nectaries 5, hemispheric, usually glabrous. *Gynoecium* 5.1-9.3 mm long, purple. *Fruit* (17.2)19-24(25.5) mm long, erect, discharge of seed-ejection type; mericarps 2.4-3.1 mm long, 1.1-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.9-1.2 mm long (mainly at the top of the mericarp); rostrum 10.5-17.5 mm long, with a narrowed apex 1.5-2.1 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 2.8-4.5 mm long, with 5 glabrous lobes. *Seeds* 1.6-2 mm long, 0.9-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 173.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 429; Lu & al. 1996: 320; Park & Kim 1997: 311; Tan & al. 1996: 211).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from May to November.

*Distribution*. This species ranges from central and northeastern China (Gansu, Hebei, Heilongjiang, Jilin, Nei Mongol, Qinghai, Shaanxi, Shanxi and Sichuan) to Mongolia, Korea and eastern Siberia (Amur, Chita, Khabarovsk and Primorye) (Fig. 174).

*Habitat*. Meadows, grassy slopes and edge of *Betula* L., and *Larix* Mill. forests; 450-3300 m.

**Discussion.** *Geranium dahuricum* is an erect perennial herb, easily identified by its short vertical rootstock with a fascicle of long and thickened roots, deeply divided leaves and medium-length petals. The indumentum consists of eglandular hairs, retrorse and appressed. However, it has some glandular hairs at the apex of the mericarp and at the base of the fruit rostrum. The petals are hairy on the base of the adaxial surface and along the nerves, usually reaching between one-third and one-half of its length. The inflorescence appears as a dichasially arranged cyme with monochasial branches. The stipules of *G. dahuricum* are usually connate for at least part of their length. In some cases they appear free, at least at some nodes of the plant. *Geranium dahuricum* usually has glabrous nectaries, although scattered hairs can be found occasionally. There is some variability in the thickness of the roots, in the degree of dissection

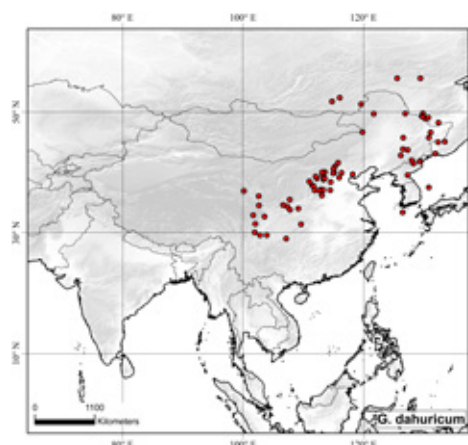

Fig. 174. Distribution of *Geranium dahuricum*.

of the leaves and in the position of the indumentum, but these features seem not to be correlated with each other, or with other characters or any particular geographical area. Thus, I consider that these variability do not deserve taxonomic recognition, but other authors differ from this point of view (Tsyrenova 2008).

*Geranium dahuricum* is quite similar to *G. soboliferum*. The latter is usually a more robust plant with longer leaf blades, longer sepals, petals, and fruits, and nectaries with hairs. *Geranium krameri* is also close to *G. dahuricum*. In addition to characters mentioned in the key, the former is more robust, with longer fruits, and its leaf blade segments have a tendency to show straight sides.

*Perennial herbs*, (25)50-129 cm tall. *Rootstock* 5-12 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with a fascicle of long and thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed or patent, eglandular hairs 0.4-0.8 mm long. *Basal leaves* in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminas (5.3)5.9-8.2(11.9) cm long, 6.7-14.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.82)0.83-0.87(0.88)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5-7, in 1 plane, middle segment rhombic, (4.3)5.4-8.5(8.8) mm wide at the base [ratio segment width at the base/middle segment length = (0.09)0.10-0.15(0.16)], 5-8(14)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.19-0.25(0.33)]; petioles up to 21 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed or patent, eglandular hairs 0.3-0.8 mm long; stipules 2.8-5.8 mm long, 1.4-3.8 mm wide, lanceolate, free or connate, papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.4)2.7-3.9(7.4)]; peduncles (12)46-70(88) mm long, with retrorse, appressed or patent, eglandular hairs 0.2-0.6 mm long; bracteoles 2.3-4.9 mm long, 0.3-1.4 mm wide, lanceolate, whorled; pedicels (21)27-37(55) mm long, with retrorse, appressed or patent, eglandular hairs 0.1-0.7 mm long. Flowers actinomorphic. *Sepals* (6.2)7.4-9.1(10) mm long, 2.3-4.3 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (0.6)0.9-1.2(1.3) mm long [ratio mucro

length/sepal length = 0.10-0.18], with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (10)11.1-13.5(14.6) mm long, (4.3)6.2-8(9) mm wide, erect-patent, rounded, without claw, light pink, hairy on the basal 1/4-1/2 of the adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.5-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.8)6.9-8.1(8.7) mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.7 mm long; anthers (1.5)1.6-1.9(2.1) mm long, unknown color. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6.9-9.6 mm long, unknown color. *Fruit* (25.6)27.1-29.7(30.8) mm long, erect, discharge of seed-ejection type; mericarps 2.4-3.4 mm long, 1.7-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and, usually, patent glandular hairs 0.4-0.7 mm long (mainly at the top of the mericarp); rostrum 16.1-20.5 mm long, with a narrowed apex 1.6-2.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and, sometimes, patent glandular hairs 0.5-0.8 mm long; stigmatic remnants (4.5)5.6-6.2(6.6) mm long, with 5 glabrous lobes. *Seeds* 1.6-2.2 mm long, 1.4-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 175.

*Pollen*. *Geranium*-type (Lu & al. 1996: 320; Park & Kim 1997: 311).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from June to September.

*Distribution*. This species ranges from eastern Siberia (Khabarovsk and Primorye), through northeastern China (Heilongjiang, Jiangsu and Jilin) and Korea to Japan (Fig. 176).

*Habitat*. Grassy fields, wet places, and humus ground in mixed and deciduous forests; 250-1900 m.

*Representative specimens examined.*

**Discussion.** *Geranium krameri* is an erect herb with a short vertical rootstock that bears a fascicle of fusiform roots. The indumentum of this species is variable, with patent eglandular hairs in some specimens and retrorse and appressed in others. In some specimens there are also some glandular hairs on the mericarp and on the fruit rostrum. The stipules of *G. krameri* are usually connate for at least part of their length. In some cases they appear free, at least at some nodes of the plant. The variability of this feature is difficult to ascertain in herbarium material and, consequently, field studies are needed to clarify the variation among individuals and populations.

*Geranium krameri* is close to *G. soboliferum* and *G. dahuricum*. The three species have a fascicle of fusiform roots, more or less connate stipules, deeply divided leaves, and large

petals that are hairy on the adaxial surface. They also share a similar inflorescence and an essentially eglandular indumentum. *Geranium krameri* has a very short rootstock in which the long, thickened roots are clustered in a fascicle. In contrast, in *G. soboliferum* and *G. dahuricum* the thickened roots are more spread out along the rootstock. *Geranium krameri* is well characterized by its shorter petals, its hairy nectaries, and its long stigmatic remnants. *Geranium soboliferum* has longer petals than *G. krameri*, although the measurements somewhat overlap. In addition, *G. soboliferum* has more deeply divided leaves than *G. krameri*, and glabrous nectaries. *Geranium krameri* has longer sepals and longer stigmatic remnants than *G. dahuricum*, also with some overlap.

**59. *Geranium soboliferum* Kom.,** Trudy Imp. S.-Peterburgsk. Bot. Sada 18(6): 433. 1901. TYPE LOCALITY: "Habitat in paludibus herbosis Manshuriaec non Koreae septentr. **Perennial herbs**, 49-89 cm tall. **Rootstock** 7-9 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with a fascicle of long and thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. **Basal leaves** in a ± deciduous rosette, cauline leaves opposite; leaf laminae (4.1)5.7-6.5(9.5) cm long, 4.4-11.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.90)0.93-0.96], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (1.6)1.8-3.3(4.4) mm wide at the base [ratio segment width at the base/middle segment length = 0.03-0.10], 8-10(18)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.31)0.33-0.50(0.60)]; petioles up to 19 cm long, without

abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules (2.8)8.4-12.3 mm long, 2.3-4.4 mm wide, triangular, connate, papery, green to brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence*

a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.6)2.7-4.9(5.8)]; peduncles 47-104(137) mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; bracteoles 2.4-6.4 mm long, 0.5-1.7 mm wide, lanceolate, whorled; pedicels (11)29-35(41) mm

long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* (7.3)8.9-10.8 mm long, 3.3-4.7 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (1.2)1.6-2.1(2.5) mm long [ratio mucro length/sepal length = 0.13-0.26], with antrorse, appressed, eglandular hairs 0.2-0.3 mm long on the abaxial surface, glabrous adaxially. *Petals* (13.4)14.2-18(20) mm long, (7.6)8-10(11.8) mm wide, erect-patent, rounded, without claw, deep reddish purple, hairy on the basal 1/3-1/2 of the adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.8-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (6.2)8.5-9.9(10.6) mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.6 mm long; anthers (1.5)1.7-2.3 mm long, blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6.7-10.8 mm long, purple. *Fruit* (28.4)30-32(35.1) mm long, erect, discharge of seed-ejection type; mericarps 3.4-3.9 mm long, 1.6-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-0.7 mm long and, sometimes, patent glandular hairs 0.7-1.1 mm long (mainly at the top of the mericarp); rostrum 18-22.9 mm long, with a narrowed apex 1.9-3.4 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long and, sometimes, patent glandular hairs 0.5-0.6 mm long; stigmatic remnants (5)5.6-6.4(6.7) mm long, with 5 glabrous lobes. *Seeds* 2.3-2.6 mm long, 1.6-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 177.

*Pollen*. *Geranium*-type (Lu & al. 1996: 320; Park & Kim 1997: 311).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from July to October.

*Distribution*. This species ranges from northeastern China (Heilong-

**Discussion.** *Geranium soboliferum* is an erect perennial herb, easily identified by its triangular, connate

stipules, deeply divided leaves, and petals that are hairy on the adaxial surface. The indumentum consists of short, retrorse, appressed eglandular hairs scattered on the base of the stem and more abundantly toward the inflorescence. The sepals with minute appressed hairs are also distinctive. Glandular hairs, when present, appear to be restricted to the apex of the mericarp and, sometimes, the base of the fruit rostrum. The petals are long, with hairs on the adaxial surface. The hairs are more abundant toward the base, although they reach half-way up the petal. Connate stipules of *G. soboliferum* were present at all nodes on all individuals examined. They are deciduous, however, and on the basal nodes they are usually wrinkled or lacking. The triangular shape of the stipules is distinctive. They appear to be greenish at first, then become reflexed and brownish when dry. The epithet *soboliferum* refers to the ability to produce soboles, or underground stolons. Yeo (2002a) stated that soboles were not present in the plants he cultivated. I found no soboles among the material studied. *Geranium soboliferum* is similar to *G. dahuricum*. The latter can be differentiated by its shorter petals, usually glabrous nectaries, and more deeply divided leaves with fewer lobes per segment.

Kurata & al. (2019) evaluate the genetic diversity and population structure of the *G. soboliferum* using microsatellite markers, with special emphasis on var. *hakusanense* and var. *kiusianum*.

*Perennial herbs*, 18-60 cm tall. *Rootstock* 3.6-8 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* trailing and ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-1 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae (2.8)3.4-4.9(7.2) cm long, 3.1-8.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.92], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 3.4-9.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.30], 5-11-lobed in distal half [ratio secondary sinus length/middle segment length = 0.21-0.38]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1 mm long; stipules 4.8-9.7 mm long, 2.9-6.6 mm wide, broadly ovate, connate, papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme with monochasial branches; cymules 1-flowered, solitary [ratio cymule length/leaf length = 1.3-3]; peduncles (9.1)24.2-75.8(154) mm long, with patent to retrorse, sometimes uncinat, eglandular hairs 0.2-1.1 mm long; bracteoles 4.3-9.7 mm long, 1-1.9 mm wide, lanceolate, opposite; pedicels 15-30(49.5) mm long, with patent to retrorse, sometimes uncinat, eglandular hairs 0.2-0.8 mm long. Flowers actinomorphic. *Sepals*

(6.5)7.6-9.2(10.1) mm long, 2.6-4.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.1-2.5 mm long [ratio mucro length/sepal length = 0.14-0.24], with antrorse to patent, eglandular hairs 0.2-1.4 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.1)14.1-18.4(20.5) mm long, 6.7-11.3 mm wide, erect-patent, rounded or rarely emarginate (notch 0.2-0.4 mm deep), without claw, light purple with a whitish base, hairy on the base of both surfaces, ciliate on the basal margin, with hairs 0.6-1.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.4-9.1 mm long, lanceolate, purple distally, paler at base, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.6 mm long; anthers 1.7-2.1 mm long, blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6.3-9.6 mm long, deep pink. *Fruit* 23.5-31.5 mm long, erect, discharge of seed-ejection type; mericarps 3.1-4.6 mm long, 1.6-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect to patent, eglandular hairs 0.3-1.2 mm long; rostrum 15.2-22.8 mm long, with a narrowed apex 1.6-3.4 mm long, not twisted, with ± patent, eglandular hairs 0.3-1 mm long; stigmatic remnants 3.5-5.6 mm long, with 5 glabrous lobes. *Seeds* 2.3-3.5 mm long, 1.5-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 179.

*Pollen*. *Geranium*-type (Park & Kim 1997: 313 [sub *G. uniflorum*]).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to October.

*Distribution*. This species is endemic to Taiwan (Fig. 180).

*Habitat*. Roadsides, exposed and rocky slopes with *Juniperus* L. and *Yushania* Keng f., *Abies* Mill. forests, and alpine grassland; 1400-3800 m.

*Additional specimens examined*. **Taiwan**. CHIAYI Co.: Pai-yunn hostel to the

top of Mt. Morrison, 23°28'N, 120°57'E, 6 Sep. 1969, *Chien-chang Hsu 6271* (TAI); Mt. Morrison, 23°28'N, 120°57'E, 6 Sep. 1969, *Kao 134* (TAI); Chiayi (Kagi), pr. Hai-unsanso, in Mt. Yu-shan (Mt. **Discussion.** *Geranium hayatanum* shares with *G. suzukii* the trailing habit and 1-flowered cymes. How-

ever, *G. hayatanum* is a more robust species very easy to recognize by its long petals, its long and connate stipules similar to those of *G. koreanum* and *G. shikokianum*, and its decumbent but not rooting stems. Both *G. hayatanum* and *G. suzukii* are endemic to Taiwan.

**61. *Geranium yoshinoi*** Makino ex Nakai, Bot. Mag. (Tokyo) 26: 258. 1912. TYPE LOCALITY: "Hab. Nippon, prov. Bitchū: Hongōmura X. 1910, fructifera, 21. VIII. 1911 floriferum (*Zensuke Yoshino*) ibidem VII. 1908 floriferum (*Yukimatsu Tamura*)". TYPE: Japan. Honshū, Bitchū, Hongōmura, 34°49'N, 133°24'E, Oct. 1910, *Z. Yoshino s.n.* (lectotype, designated by Aedo 2017a: 46: TI!).

*Perennial herbs*, 34-94 cm tall. *Rootstock* 5.7-8.7 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with a fascicle of long and thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.7 mm long. *Basal leaves* in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminas (4.9)5.4-7.8(9.3) cm long, 5.2-10.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.73)0.78-0.88], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (7.1)8.1-11.4(15.5) mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.27], 7-9-lobed in distal half [ratio secondary sinus length/middle segment length = 0.18-0.33];

petioles up to 56 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long; stipules 2.8-6.9 mm long, 0.8-4.1 mm wide, lanceolate, free or connate, papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.3-6.6]; peduncles 25-97 mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; bracteoles 1.9-4.3 mm long, 0.4-0.9 mm wide, lanceolate, whorled; pedicels 17-48 mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. Flowers actinomorphic. *Sepals* 6.2-7.4(7.8) mm long, 2.5-4.4 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.7-1.6 mm long [ratio mucro length/sepal length = 0.12-0.21], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.4 mm long on the abaxial surface, glabrous adaxially. *Petals* (9.7)11-13.2(14.2) mm long, 3.2-9 mm wide, erect-patent, rounded, without claw, pink, hairy on the basal 1/4-1/2 of the adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.4-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.5-8.5 mm long, lanceolate, slightly dilated at the base, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.4 mm long; anthers 1.3-2.1 mm long, unknown color. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 5.3-8.1 mm long, unknown color. *Fruit* 18.7-26.2 mm long, erect, discharge of seed-ejection type; mericarps 2.7-4 mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.7 mm long; rostrum 10.6-17.3 mm long, with a narrowed apex 1.3-3.3 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants (3.6)3.8-4.3(4.6) mm long, with 5 glabrous

lobes. *Seeds* 2.1-2.4 mm long, 1.4-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 181.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from July to October.

*Distribution*. This species ranges from southern Honshū to Kyūshū, in Japan (Fig. 182).

*Habitat*. Moist, grassy places; 350-950 m.

*Additional specimens examined*. **Japan**. HONSHŪ: Hiroshima prefecture, Sandakyo,

**Discussion.** *Geranium yoshinoi* is similar to *G. krameri*. Its status as a distinct taxon is supported by a combination of minor features, these, however, usually with some overlap. The most important is the length of the stigmatic remnants, usually longer in *G. krameri* than in *G. yoshinoi*. In addition, *G. yoshinoi* has less deeply divided leaves, with fewer lobes per segment, the middle segment wider, and shorter sepals, anthers, and fruits. The indument is similar to that of *G. krameri* but with slightly shorter hairs. The geographical distribution of *G. yoshinoi* also supports its taxonomic recognition: it appears to be restricted to southern Honshū and Kyūshū, whereas *G. krameri* occurs northward.

**62. *Geranium yesoense*** Franch. & Sav., Enum. Pl. Jap. 2: 305. 1878, ["Yedoense"]. TYPE LOCALITY: "Hab. in insulâ Yeso, Hakodate, unde habuit Dr Savatier (n. 2446)". TYPE: Japan. *Perennial herbs*, 15-77 cm tall. *Rootstock* 6.9-11.3 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, ± appressed, eglandular hairs 0.4-0.9 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminae (3.8)4.1-6.7(9.9) cm long, 4.6-14.3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.61)0.77-0.83(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 5-8.8(16) mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.30], (3)7-13-lobed in distal half [ratio secondary sinus length/middle segment length = 0.25-0.47]; petioles up to 45 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.4-1.1 mm long; stipules (2)5.2-8.7 mm long, 1-5.3 mm wide, ovate, free or connate, papery, brown, with scattered, eglandular hairs on both surfaces and on the

margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.4-3.2]; peduncles 39-71(132) mm long, with retrorse, ± appressed, eglandular hairs 0.2-0.8 mm long; bracteoles 3.6-8.4 mm long, 0.8-1.4 mm wide, lanceolate, whorled; pedicels 16-52 mm long, with retrorse, ± appressed, eglandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* (7)8.6-9.7(11.1) mm long, 3.3-5.8 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1.2-2.6 mm long [ratio mucro length/sepal length = 0.14-0.33], with ± erect-patent, eglandular hairs 0.3-1.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (13.2)15-17.2(18.7) mm long, 5.6-10.8 mm wide, erect-patent, rounded, without claw, pink or white, hairy on the basal 1/4-1/3 of the adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.4-1.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.4-10.5 mm long, lanceolate with an abruptly narrowed apex, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.8 mm long; anthers 1.6-2.5 mm long, yellow with bluish lines. Nectaries 5, hemispheric, usually glabrous. *Gynoecium* 6.2-10.3 mm long, red. *Fruit* 26.2-36.4 mm long, erect, discharge of seed-ejection type; mericarps 2.2-4.5 mm long, 1.7-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.4-1.1 mm long and, rarely, patent glandular hairs 0.6-1.6 mm long; rostrum 17.7-25.7 mm long, with a narrowed apex 2.5-4.3 mm long, not twisted, with ± patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants (3.3)3.6-3.9(4.3) mm long, with 5 glabrous lobes. *Seeds* 2.4-3.1 mm long, 1.4-2.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 183.

*Pollen*. *Geranium*-type (Park & Kim 1997: 311).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from July to October.

*Distribution*. This species ranges from central Honshū and Hokkaidō, in Japan to Kuril Is., in Russia (Fig. 184).

*Habitat*. Sandy ground near beaches, meadows on coastal terraces, sunny grassy slopes, and fields; 0-2900 m.

**Discussion.** *Geranium yesoense* is in many aspects similar to *G. soboliferum*. Both are erect perennial herbs with connate stipules, deeply divided leaves, and large petals that are hairy

Fig. 183. *Geranium yesoense*. a. Habit. b, c. Stipules. d. Leaf indument, adaxial surface. e. Leaf indument, abaxial surface. f. Bracteoles. g. Flower without petals and sepals. h. Sepal. i. Fig. 184. Distribution of *Geranium yesoense*.

on the adaxial surface. The indument and inflorescence are quite similar in both species, but the eglandular hairs of *G. yesoense* are a bit longer than those of *G. soboliferum*. It is interesting to note that the hairs of the abaxial surface of the sepals are usually a good feature to discriminate *G. yesoense*. The sepals are covered by minute appressed hairs plus erect-patent and longer hairs, present mainly on nerves. As in *G. soboliferum*, glandular hairs of *G. yesoense* are restricted to the apex of the mericarp, although they are found with less frequency than in the former species. The petals of *G. yesoense* are hairy on adaxial surface, at least on the basal 1/4. In some cases the hairs reach the basal 1/3 or more along the petal nerves. The connate stipules of *G. yesoense* are most similar to those of *G. shikokianum*, although not as wide. They are usually connate for at least part of their length. In some cases they appear free, at least at some nodes of the plant. Nevertheless, in a portion of herbarium specimens it was difficult to ascertain, since stipules are early deciduous and many times they are wrinkled or lacking from basal nodes. The rootstock of *G. yesoense* also resembles the rootstock of *G. shikokianum*: short, vertical, and bearing long, thickened non-fasciculate roots. *Geranium soboliferum* and *G. krameri* appear to have the roots that are more fasciculate. The leaves of *G. yesoense* are less deeply divided and with wider segments than those of *G. soboliferum*, although there is some overlap. The nectaries of *G. yesoense* are usually glabrous, in contrast with those of *G. soboliferum*, which have an apical tuft of hairs. In rare cases, however, scattered hairs around the nectaries in *G. yesoense* can be found.

Akiyama (2001) recognized three varieties into *G. yesoense* (var. *yessoense*, var. *nipponicum* and var. *pseudopalustre*) on the basis of the relative degree of leaf incision and on the relative density of the sepal hairs. Wakasugi & al. (2017) carried out a detailed studied both morphological and DNA variability

of *G. yesoense* and concluded that “such groups cannot be clearly distinguished on the basis of either morphological or molecular evidence”. Therefore, they proposed to synonymize these varieties to *G. yesoense*, as was done in Aedo (2017). In contrast to these studies, Kurata & al. (2021a) suggested that their work based on single nucleotide polymorphism data and chloroplast genome sequences consistently indicated that these varieties “are distinct and independent evolutionary units”. However, they found that some high mountain populations are not fully congruent with this pattern. Furthermore, they did not present arguments against the morphological continuity found by Wakasugi & al. (2017).

The species epithet was spelled both *yedoense* and *yessoense* in the original publication. The name of the mountain for which the species was named was given as Mt. Yeso. The spelling *yessoense* has been used subsequently and is accepted here.

*Geranium yesoense* is an endemic to central and northern Japan reaching eastern Kuril Islands. It has also been recorded in Sakhalin Is. (quoted by Novoselova 1999: 131). Unfortunately, no specimen from this island has been available.

---

**The Columbinum Group**—This group comprises two annual species with deeply divided leaves, usually opposite, free stipules, 2-flowered cymules arranged in monochasial inflorescence, short petals, lanceolate staminal filaments, and eglandular indumentum.

**Discussion.** *Geranium columbinum* is an annual herb that may be easily distinguished by its accrescent sepals, its deeply divided leaves, and its eglandular indumentum. *Geranium columbinum* is sometimes mistaken for *G. dissectum* because of its deeply dissected leaves. The latter has, however, glandular indumentum and mericarps without the basal callus (it is replaced by a prong). The differences between *G. columbinum* and *G.*

*carolinianum* (another annual species with accrescent sepals) are addressed under the later species.

**64. *Geranium schrenkianum*** Trautv., Bull. Soc. Imp. Naturalistes Moscou 57(1): 53. 1882. *G. gracile* Schrenk, Bull. Cl. Phys.-Math. Acad. Imp. Sci. Pétersbourg 3: 308. 1845, nom. illeg., non Ledeb. 1837. TYPE LOCALITY: "Hab. in montibus Chantau". TYPE: Kazakhstan. Chantau, Songaria, 46°00'N, 80°00'E, 26 June 1843, A. Schrenk 6179 (lectotype, designated by Bobrov 1949: 14, LE!; isolectotypes, BMI!, P-00757899!, TK-001294 image!).

*Annual herbs*, 6-64 cm tall. *Stem* erect, leafy, with antrorse, appressed, eglandular hairs 0.2-0.4 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae 1.5-2.9(4.4) cm long, 2.2-2.7(5.3) cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 1-1.3(2.1) mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.13], 3-4(8)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.26-0.41]; petioles up to 7 cm long, without abscission zone, terete, not swollen, not deflexed in age, with antrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules 2.1-5 mm long, 0.5-1 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary [ratio cymule length/leaf length = 1.1-2.9]; peduncles 12-48 mm long, with antrorse, appressed, eglandular hairs 0.2-0.3 mm long; bracteoles 1.4-2.8 mm long, 0.3-0.4 mm wide, lanceolate, whorled; pedicels 14-33 mm long, with antrorse, appressed, eglandular hairs 0.2-0.3 mm long. Flowers actinomorphic. Se-

*pals* 4.1-6 mm long, 1.5-3 mm wide, ovate, smooth, not accrescent, nerves 3, mucro 1.6-3 mm long [ratio mucro length/sepal length = 0.34-0.41], with antrorse, appressed, eglandular hairs 0.2-0.4 mm long on the abaxial surface (mainly on the nerves), glabrous adaxially. *Petals* 3-4 mm long, 1.5-2 mm wide, erect-patent, emarginate

(notch ca. 0.3 mm deep), without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.5-2.6 mm long, lanceolate, white, glabrous except for a some cilia 0.1-0.2 mm long on the proximal half; anthers 0.3-0.5 mm long, unknown color. Nectaries

5, hemispheric, glabrous. *Gynoecium* 2-4 mm long, pink. *Fruit* 13-17.4 mm long, erect, discharge of seed-ejection type; mericarps 2-3.6 mm long, 1.2-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with scattered antrorse, eglandular hairs 0.1-0.3 mm long; rostrum 9-12 mm long, with a narrowed apex 1-2.1 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.7-1.2 mm long, with 5 hairy lobes. *Seeds* 1.8-2.4 mm long, 1-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 188 a-i.

*Pollen*. *Geranium*-type (Aedo 2003: 129).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to July.

*Distribution*. This species ranges from eastern Russia (Orenburg, Rostov, Samara and Volgograd) to Kazakhstan (Fig. 189).

*Habitat*. Moist places on pebbly or sandy beds of rivers; 0-700 m.

*Additional specimens examined*. **Kazakhstan**. AKMOLA: Akmolinskaya obl., vass. r. Tergsakkana, Mt. Kokshetau, SW slope, 52°45'N, 68°59'E, 28 June 1957, *Grubov* 28 (LE); Tzelinograd prov., systema fl. Tersakkan, montes Kokschetau, 52°45'N, 68°59'E, 12 July 1957, *Grubov & Popova* 4379 (LE).

**Discussion.** *Geranium schrenkianum* is a species quite similar to *G. columbinum* that some authors have included in the synonymy of the latter (Webb & Ferguson 1968: 198). According to Bobrov (1949: 13), *G. schrenkianum* is characterized by its smaller flowers. The species was reevaluated by Aedo (2003), showing that *G. schrenkianum* has antrorse, appressed hairs on the stem, petioles, peduncles, and pedicels, while *G. columbinum* has retrorse hairs in all these parts. Additionally, *G. schrenkianum* has shorter sepals, petals and fruits than *G. columbinum*. These two species have allopatric areas.

**The Sibiricum Group**—The species of this group are perennials, trailing to ascending, sometimes rooting at the nodes, usually with opposite leaves, free and narrow stipules, 1-2-flowered cymules arranged in monochasial inflorescence and petals of small size, with short hairs at the base.

**65. *Geranium arnottianum*** Steud., Nomencl. Bot. ed. 2, 1: 677. 1840. *Geranium affine* Wight & Arn., Prodr. Fl. Ind. Orient.: 133. 1834, nom. illeg., non Ledeb., 1831. *Perennial herbs*, 12-42 cm tall. *Root-stock* 6-7 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, unknown roots. *Stem* prostrate to as-

ending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.4-1.4 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas (2.4)2.7-3.9(4.6) cm long, 2.8-5.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.82)0.84-0.87(0.91)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (2.8)3.3-4.4(5.4) mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.18(0.21)], 8-12(15)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.27)0.29-0.34(0.39)]; petioles up to 7.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.6-1.5 mm long; stipules 5.4-7.3(7.6) mm long, 0.7-2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on both surfaces, and on the margin. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary [ratio cymule length/leaf length = (1)1.9-2.2(3.1)]; peduncles (8.1)35-77(85) mm long, with patent, eglandular hairs 0.2-1.3 mm long; bracteoles (3)3.8-5(5.2) mm long, 0.3-0.7 mm wide, lanceolate, usually whorled; pedicels (14.8)18-22.9(26.3) mm long, with patent, eglandular hairs 0.3-1.3 mm long. Flowers actinomorphic. *Sepals* (5.6)5.9-7.2(7.9) mm long, 1.9-3 mm wide, lanceolate, smooth, accrescent, nerves 3, mucro (0.6)0.7-1.1(1.2) mm long [ratio mucro length/sepal length = (0.11)0.12-0.16(0.17)], with ± patent, eglandular hairs 0.6-1.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.3)8.4-9.7(12.2) mm long, (4.5)4.7-6.2(7.7) mm wide, erect-patent, emarginate (notch 0.2-1.4 mm deep), without claw, unknown color, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.3-4.7(5.5) mm long, lanceolate, unknown color,

with scattered hairs 0.1-0.3 mm long on abaxial surface and margin; anthers 1.2-1.3 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoeceum* 4.2-6.5 mm long, unknown color. *Fruit* (18.1)19-21(21.9) mm long,

erect, discharge of seed-ejection type; mericarps 3.3-4.3 mm long, 1.4-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown,

with  $\pm$  patent, eglandular hairs 0.7-1.7 mm long; rostrum 11.8-15 mm long, with a narrowed apex 1-2.1 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.5 mm long; stigmatic remnants (1.8)2.1-2.5 mm long, with 5 hairy lobes. *Seeds* 2.6-2.9 mm long, 1.4-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 190.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to November.

*Distribution*. This species is endemic to southern India (Kerala and Tamil Nadu) (Fig. 191).

*Habitat*. Grassland; 1750-2300 m.

*Additional specimens examined*. **India**.

**Discussion.** *Geranium arnottianum* is a prostrate to ascending herb. Its underground parts are poorly known through the scarce herbarium material available. Nevertheless, it seems to have a narrow, vertical rootstock. Stems, leaves, petioles, and inflorescence are covered by long, eglandular hairs, more densely when young. Among the material studied, cymules are almost always 2-flowered. Sepals are accrescent and fruits have a distinct narrowed apex and long stigmatic remnants. However, its more distinctive features are its relatively long, emarginated petals and its leaves with a rhombic middle segment, which have many lobes. *Geranium arnottianum* is close to *G. nepalense*, a species widespread on the Himalayas that have some isolated localities in Sri Lanka and Sumatra. Some authors have synonymized both species. However, *G. arnottianum* is an endemic from South India, easily to recognize from *G. nepalense* by its long petals, distinctive leaves, and long stigmatic remnants.

**Perennial herbs**, 10-72 cm tall. **Rootstock** 2-5.8 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** trailing and ascending, leafy, sometimes root-

ing at nodes, stolons absent, without vegetative stems, with patent to retrorse, appressed, eglandular hairs 0.2-1.3 mm long. **Basal leaves** in a ± persistent rosette, cauline leaves opposite; leaf laminas (2.3)2.9-3.8(5.3) cm long, 2.7-6.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.78)0.80-0.87(0.90)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment broadly rhombic, 3.2-5.6(6.5) mm wide at the base [ratio segment width at the base/middle segment length = (0.13)0.16-0.22(0.23)], 6-10(13)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.11)0.19-0.23(0.28)]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.2-1.5 mm long; stipules (3.7)5.4-8.2(11.9) mm long, 0.7-2.4 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, ± glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 1-2(3)-flowered, solitary [ratio cymule length/leaf length = (0.7)1.2-2.1]; peduncles (12)40-71(83) mm long, with patent to retrorse, eglandular hairs 0.3-1.3 mm long; bracteoles (2.7)3.4-4.5(5.2) mm long, 0.4-0.9 mm wide, lanceolate, opposite or whorled; pedicels (10.4)15-22(31.9) mm long, with patent to retrorse, eglandular hairs 0.2-1 mm long. **Flowers** actinomorphic. **Sepals** (4.1)4.4-5.5(5.8) mm long, 1.6-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.4)0.7-0.9(1) mm long [ratio mucro length/sepal length = (0.10)0.15-0.20(0.23)], with ± patent, eglandular hairs 0.4-1 mm long on the abaxial surface, glabrous adaxially. **Petals** (4.4)5-5.6(6.3) mm long, (2)2.7-3.3(4) mm wide, erect-patent, rounded or slightly emarginate, without claw, white or pale pink, rarely deep pink, with scattered hairs on the base of both surfaces and on the basal margin, with hairs 0.1-0.4 mm long.

*Stamens* 10, both whorls bearing anthers; filaments (1.8)2.5-3.1(3.8) mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.4 mm long; anthers (0.3)0.5-0.7(0.9) mm long, blue. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.9-4 mm long, purple. *Fruit* (14)15.1-17.8(18.8) mm long, erect, discharge of seed-ejection type; mericarps 2.5-3.2 mm long, 1.3-1.7

mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-1.2 mm long; rostrum 9.3-13.9 mm long, with a narrowed apex 0.9-2 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long; stigmatic remnants 0.8-1.2(1.4) mm long, with 5 hairy

lobes. *Seeds* 1.9-2.4 mm long, 1.1-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 192, 193.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 433; Gagnepain 1903: 87; Park & Kim 1997: 311; Perveen & Gaiser 1999: 266; Tan & al. 1996: 213).

*Chromosome number.*  $2n = 26, 28$ .

*Phenology.* Collected in flower from January to December.

*Distribution.* This species ranges from Afghanistan to eastern China through Pakistan, India, Nepal, Burma, Thailand, Laos and Vietnam and it is introduced in Sri Lanka, Sumatra, Australia and Brazil (Fig. 194).

*Habitat.* Disturbed areas, roadsides, fields, meadows and forest edges; 100-3800 m.

*Discussion.* *Geranium nepalense* is a trailing and ascending perennial, sometimes rooting at the nodes, with short petals and eglandular indumentum. This species is sometimes difficult to distinguish from *Geranium sibiricum*. Normally, at least some cymules in each plant of *G. nepalense* are 2-flowered, but 1-flowered cymules are not infrequent. In extreme forms, 2-flowered cymules can be difficult to locate. Information from herbarium specimens is not enough to understand this variability, and further field studies could be necessary. *Geranium nepalense* has leaves with broader segments than in *G. sibiricum* (with the widest point nearest to the apex), shorter narrowed apex of the rostrum, and longer sepal mucro. Additionally, *G. nepalense* is sometimes rooting at the nodes, which has not been observed in *G. sibiricum*. Distribution of *G. nepalense* seems to be more southern than that of *G. sibiricum*.

The lectotype of *G. nepalense* was chosen on an illustration, since no other original material has been located. An epitype is also designated for purposes of the precise application of the name.

*Perennial herbs*, 15-95 cm tall. *Root-stock* 2-5.3 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-1 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminas (1.7)3.2-5.1(5.8) cm long, 2.2-7.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.83)0.88-0.91(0.93)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment narrowly rhombic, (3.2)3.9-4.7(5.5) mm wide at the base [ratio segment width at the base/middle segment length = (0.10)0.11-0.18(0.24)], (7)9-14-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.20-0.25(0.28)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.5 mm long; stipules 2.6-9.5 mm long, 0.6-1.9 mm wide, lanceolate to subulate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, ± glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1(2)-flowered, solitary [ratio cymule length/leaf length = (0.6)0.7-1.5(2.8)]; peduncles (9)17-34(87.6) mm long, with patent to retrorse, eglandular hairs 0.2-0.9 mm long; bracteoles 1.1-5 mm long, 0.3-1 mm wide, linear-lanceolate, opposite; pedicels

(18)19-27(35) mm long, with patent to retrorse, eglandular hairs 0.2-0.8 mm long. Flowers actinomorphic. *Sepals* (3.7)4.5-5.8(6.4) mm long, 1.8-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.9)1-1.5(1.6) mm long [ratio mucro length/sepal length = (0.18)0.23-0.28(0.35)], with patent to antrorse, ± appressed, eglandular hairs 0.2-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* 4-5.4(5.8) mm long, (1.8)1.9-2.4(3) mm wide, erect-patent, rounded or slightly emarginate, without claw, white or pale pink with purplish veins, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments (2.4)2.5-2.8(3.1) mm long, lanceolate, yellow, glabrous on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.3 mm long; anthers (0.3)0.5-0.6(0.7) mm long, blue. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 2.4-3.6 mm long, yellow. *Fruit* (13.9)15-18(19.4) mm long, erect, discharge of seed-ejection type; mericarps 2.8-3.6 mm long, 1.1-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at apex), without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.1-1.5 mm long; rostrum 8.5-13.9 mm long, with a narrowed apex 0.3-1 mm long, not twisted, with antrorse, eglandular hairs 0.1-0.5 mm long; stigmatic remnants 0.8-1.3 mm long, with 5 hairy lobes. *Seeds* 2-2.8 mm long, 1.1-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 195.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 433; Lu & al. 1996: 320; Park & Kim 1997: 311; Stafford & Blackmore 1991: 74; Tan & al. 1996: 213).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from February to December.

*Distribution*. This species ranges from central and eastern Europe and the Caucasus to Japan through Sibe-

ria, Kazakhstan, Tadzhikistan, Uzbekistan, Pakistan, Mongolia, China and Korea, and it is introduced in north-eastern U.S.A. (Fig. 196).

**Habitat.** Waste places, roadsides, fields and forest edges; 0-4300 m.

**Discussion.** *Geranium sibiricum* is an erect to ascending perennial, characterized by 1-flowered cymules, short petals, leaves with narrow segments, and eglandular indumentum. Some specimens occasionally have 2-flowered cymules, although most of the nodes have 1-flowered cymules. Some authors have suggested that European plants are characterized by pink to pinkish violet petals and villous vegetative parts, and Siberian plants by white to pale pink petals and short and appressed hairs. Through the whole area of the species, these characters appear mixed in different combinations, which does not support such a division.

Mirek (1980) indicated that this species is also found in Poland. Unfortunately, it has not been possible to study any herbarium voucher of such record.

*Geranium nepalense* f. *roseum* H. Hara, J. Jap. Bot. 22: 172. 1948. *Geranium thunbergii* f. *roseum* (H. Hara) Murata, Acta Phytotax. Geobot. 17: 172. 1958. TYPE LOCALITY: [not stated, probably from Japan]. TYPE: Japan. Without definite locality, H. Hara s.n. (no original material located).

*Perennial herbs*, 20-70 cm tall. *Root-stock* 2-10 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* trailing and ascending, leafy, sometimes rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, appressed, eglandular hairs 0.3-1.4 mm long and, sometimes, patent, glandular hairs 0.8-1.3 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae (2.4)2.7-5.1(6.4) cm long, 3.2-7.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.73)0.75-0.86(0.91)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (4)5.4-8.3(12) mm wide at the base [ratio segment width at the base/middle segment length = (0.17)0.22-0.27(0.28)], 5-7(8)-lobed in distal half [ratio secondary sinus length/middle segment

length = (0.11)0.15-0.18(0.22)]; petioles up to 23 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.2 mm long and, sometimes, patent, glandular hairs 0.5-1.2 mm long; stipules 4.5-11.9 mm long, 0.8-2.6 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.6)1.1-2.5]; peduncles (22)31-65(139) mm long, with patent, eglandular hairs 0.2-0.9 mm long and, sometimes, patent, glandular hairs 0.4-1 mm long; bracteoles 2.2-4.8 mm long, 0.4-1.6 mm wide, linear-lanceolate, whorled; pedicels (8.5)13-25(32.9) mm long, with patent, eglandular hairs 0.2-1 mm long and, usually, patent, glandular hairs 0.6-1.1 mm long. *Flowers* actinomorphic. *Sepals* (5.1)5.4-7.3(8.1) mm long, 1.9-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.8)1-1.2(1.9) mm long [ratio mucro length/sepal length = 0.12-0.25], with patent to antrorse, eglandular hairs 0.1-0.9 mm long and patent, glandular hairs 0.2-1.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.8)7.3-8.3(9) mm long, (3.2)3.8-5.1(5.7) mm wide, erect-patent, rounded or retuse, without claw, white or purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.1-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments (3.2)3.6-4.1(4.7) mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.7 mm long; anthers 0.8-0.9(1.1) mm long, blue. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 3.7-5.3 mm long, pink. *Fruit* (19.1)20-23(26.6) mm long, erect, discharge of seed-ejection type; mericarps 2.5-3.6 mm long, 1.4-1.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black or deep brown, with ±

patent, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.6-1.5 mm long; rostrum 13.2-20.4 mm long, with a narrowed apex 0.5-1.8 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and patent, glandular hairs 0.4-0.8 mm long; stigmatic remnants 1.6-2.3 mm long, with 5 hairy lobes. Seeds 1.7-2.2

mm long, 1.3-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 197.

*Pollen.* *Geranium*-type (Park & Kim 1997: 313).

*Chromosome number.*  $2n = 28$ .

*Phenology.* Collected in flower from January to December.

*Distribution.* This species ranges from central and eastern China, Taiwan, Korea to Japan and it is introduced in Germany, northeastern U.S.A. and southern Brazil (Fig. 198).

*Habitat.* Seashores, roadsides, fields, waste grounds, weedy areas, rocky hillsides, grassland, along streams and edge of evergreen and deciduous forests; 0-2350 m.

*Representative specimens examined.*

**Discussion.** *Geranium thunbergii* is a trailing and ascending herb sometimes rooting at the nodes. This species has sometimes been submerged in *Geranium nepalense*. However, it is well characterized by the presence of glandular hairs (sometimes restricted to sepals) and by longer petals, sepals, and fruit. Additionally, leaves of *G. thunbergii* have few lobes, and its mericarps are darker. Distribution of *G. thunbergii* seems to be more eastern than those of *G. nepalense*, being alone in Taiwan, Japan, and Korea.

Tsuchimatsu & al. (2014) studied the herbivore pressure associated with the flower color polymorphism of *G. thunbergii*, founding more severe damage in white flowers.

**Discussion.** *Geranium wilfordii* is a perennial herb, erect and with relatively short petals. It is easily identified by its leaves, which are triangular in outline and with three segments. In some specimens, the blade of basal leaves can have two more very short

segments at the base, producing leaves with a  $\pm$  pentagonal outline. These plants could be confused with *G. thunbergii*, which has longer petals. Basal cauline leaves are usually alternate in *G. wilfordii*, but few herbarium specimens with whole plants are available to ascertain the variability of this feature. Glandular indumentum is variable, sometimes even in the same specimen.

Rostanski & Tokarski (1973) indicated that this species is also found in Poland. Unfortunately, it has not been possible to study any herbarium voucher of such record.

**Perennial herbs**, 15-60 cm tall. **Rootstock** 3.2-4.8 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with few thickened,  $\pm$  fasciculate roots. **Stem** trailing and ascending, leafy, rooting at nodes, stolons absent, without vegetative stems, with scattered, retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.5 mm long. **Basal leaves** in a deciduous rosette, cauline leaves alternate (usually

1) in middle of shoot and upper opposite; leaf laminas (1.4)2.5-4(4.5) cm long, 1.8-5.8 cm wide, not peltate, palmatisect, triangular in outline, base cordate, not coriaceous, with nerves not projected, pilose, with scattered, appressed, eglandular hairs on both surfaces; segments 3, in 1 plane, middle segment rhombic, 0.4-1.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.02-0.04], 5-11-lobed in distal half [ratio secondary sinus length/middle segment length = 0.11-0.38]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.6 mm long; stipules 1.9-9.6 mm long, 0.6-1.8 mm wide, lanceolate, free, papery, brownish red, glabrous on both surfaces or with scattered, eglandular hairs on abaxial surface and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.4)1.1-2.6]; peduncles 12-26 mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.4 mm long; bracteoles 1.3-3.6 mm long, 0.3-0.7 mm wide, lanceolate, whorled; pedicels 12-20.4 mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.4 mm long. Flowers actinomorphic. *Sepals* (4)4.7-5.6(6.4) mm long, 1.4-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-1.5 mm long [ratio mucro length/sepal length = 0.09-0.32], with abundant, antrorse, appressed, eglandular hairs ca. 0.1 mm long on the surface and scattered, patent, glandular hairs 0.8-1.5 mm long on nerves and margins of the abaxial surface, glabrous adaxially. *Petals* (4.3)4.5-5.8(6.7) mm long, 2.1-3.4 mm wide, erect-patent, rounded, without claw, white, with scattered hairs on the base of both surfaces and on the basal margin, with hairs 0.1-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.7-3.5 mm long, lanceolate with an abruptly narrowed apex, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.3 mm long; anthers

0.5-0.7 mm long, pink. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-4 mm long, pink. *Fruit* 14-19.2 mm long, erect, discharge of seed-ejection type; mericarps 2.4-3 mm long, 1.2-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-0.7 mm long and, usually, patent glandular hairs 0.6-1.1 mm long (restricted to the top of the mericarp); rostrum 10.9-13.7 mm long, with a narrowed apex 0.5-1 mm long, not twisted, with erect-patent, eglandular hairs ca. 0.1 mm long; stigmatic remnants 0.7-1.4 mm long, with 5 hairy lobes. *Seeds* 1.9-2.2 mm long, 1.2-1.6 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 201.

*Pollen*. *Geranium*-type (Park & Kim 1997: 313).

*Chromosome number*.  $2n = 28+2B$ .

*Phenology*. Collected in flower from July to October.

*Distribution*. This species ranges from South Korea to Japan (central Honshū to Kyūshū and Shikoku) (Fig. 202).

*Habitat*. Grassy slopes, and humid, deciduous forests; 250-1550 m.

*Additional specimens examined*. **Japan.**

*Discussion*. *Geranium tripartitum* is easily recognized by its distinctive leaves. They are composed of three rhombic segments divided to the base. Each lateral segment has a deep basal lobe which appears as an additional segment. *Geranium tripartitum* has a short and vertical rootstock,

with few thickened roots, and some prostrate to ascending aerial stems, rooting at nodes. At the rooting nodes, a distinctive bud composed of stipules is found. From each of these buds an aerial flowering stem arises.

Leaves of the basal (and medial) part of the stem are alternate, while those of the inflorescence are usually opposite. The indument of *G. tripartitum* is largely composed of eglandular, short, appressed hairs. Glandular

Fig. 202. Distribution of *Geranium tripartitum*.

hairs are only present on the sepals and on the apex of the mericarp. Particularly characteristic is the indument of the sepals, which have short and appressed eglandular hairs on the surface and long, patent glandular hairs on the nerves and margin. Plants without glandular hairs on the sepals occasionally occur; they were described as *G. tripartitum* f. *pilosellum* H. Hara, but do not merit taxonomic recognition. *Geranium tripartitum* has some important similarities with *G. wilfordii*. Both share a similar rootstock, petal size, staminal filament type, and fruit shape. However, the latter species has palmatifid leaves (usually with three lobes), and an erect stem not rooting at the nodes. *Geranium wilfordii* sometimes presents a sepal indument similar to that previously described for *G. tripartitum*, but it is variable in this feature. *Geranium thunbergii* is also similar to *G. tripartitum*, but *G. thunbergii* has palmatifid leaves with five segments, longer petals, and usually glandular hairs on peduncles and pedicels.

**71. *Geranium suzukii*** Masam., J. Soc. Trop. Agric. 3: 392. 1931. *Geranium nepalense* var. *suzukii* (Masam.) Murata, Acta Phytotax. Geobot. 17: 172. 1958. TYPE LOCALITY: "Hab. Taiheizan. Toganô Jul. 16, 1929, Leg. Suzuki, no. 392 (Typ. in Herb. Taihoku Imp.

Univ.)". TYPE: China. Taiwan. Taiping-shan, 24°29'N, 121°31'E, 16 July 1929, S. Suzuki 392 (holotype, TAI image!).

*Perennial herbs*, 18-45 cm tall. *Rootstock* 2-3 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* trailing, leafy, rooting at nodes, stolons absent, without vegetative stems, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae (1.1)1.9-2.4(3.3) cm long, 1.5-3.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.74-0.84], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 1.4-4.6 mm wide at the base [ratio segment width at the base/middle segment length = 0.12-0.23], 3(5)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.13-0.30]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.4 mm long; stipules 2.6-5.4 mm long, 0.5-1.2 mm wide, linear-lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.9)1.1-3]; peduncles (25)37-50(72) mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.6 mm long; bracteoles 2.6-4 mm long, 0.3-0.7 mm wide, linear-lanceolate, opposite; pedicels 11-36 mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.1-0.4 mm long. Flowers actinomorphic. *Sepals* (4.1)4.4-5.8(6.4) mm long, 1.3-2.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.9-1.8 mm long [ratio mucro length/sepal length = 0.14-0.43], with antrorse, appressed, eglandular hairs 0.1-0.9 mm long and scattered, patent, glandular hairs 0.5-1.3 mm long on the

abaxial surface,  $\pm$  hairy adaxially. *Petals* (5.2)7.2-8.4(12.7) mm long, 2.6-6.2 mm wide, erect-patent, rounded, without claw, white or pale pink with purplish veins, with scattered hairs on the base of both surfaces and on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2-4.5 mm long, lanceolate with an abruptly narrowed

apex, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.3 mm long; anthers 0.5-1 mm long, blue. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 2.9-5 mm long, green. *Fruit* 17-20 mm long, erect, discharge of seed-ejection type; mericarps 2.5-3.5 mm long, 1.2-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth,

*Discussion.* *Geranium suzukii* is a  
trailing herb, consistently rooting  
at the nodes. It usually has glandu-  
lar hairs restricted to the sepals and  
sometimes on the fruit, and 1-flow-  
ered cymules. The petals are white  
or pale pink, which was stated in the  
protologue and observed in cultivat-  
ed specimens, not yellow as some au-  
thors have mentioned (Huang 1993).  
*Geranium suzukii* appears to be close  
to *G. sibiricum* from which it differs  
by its longer petals, leaves with ob-  
triangular segments (and with few  
lobes), and glandular indument of the  
sepals. *Geranium suzukii* is endemic  
to the central mountains of Taiwan,  
while the nearest localities of *G. si-  
biricum* are in central China, about  
1200 km to the northwest. The most  
similar sympatric species is *G. thun-  
bergii*, which is distinguished by its  
leaves with rhombic and more lobed  
segments and its 2-flowered cymules  
with glandular indument.

**72. *Geranium frigidurbis* Moerman,**  
*Blumea* 24(2): 469. 1978. TYPE LOCALITY:  
"Bünnemeijer 11906 (L; iso in BO, n.v.),  
Celebes (Bonthain)". TYPE: Indonesia.  
Celebes, Bonthain, 5°21'S, 119°56'E, 8  
June 1921, *H.A. Bünnemeyer* 11906 (ho-  
lotype, L-0018342!; isotypes, BO, K!).

*Perennial herbs*, 20-29 cm tall.  
*Rootstock* 3-3.5 mm in diameter,  $\pm$   
vertical, not tuberculate, not tur-  
nip-shaped, without thickened roots.  
*Stem* prostrate, leafy, sometimes  
rooting at nodes, stolons absent,  
without vegetative stems, with retror-  
se, appressed, eglandular hairs  
0.2-0.4 mm long. *Basal leaves* in a  $\pm$   
persistent rosette, cauline leaves op-  
posite; leaf laminae (1.2)1.4-1.8(3.1)  
cm long, 1.3-4 cm wide, not peltate,  
palmatifid [ratio main-sinus length/  
middle segment length = (0.74)0.76-  
0.83(0.84)], polygonal in outline, base  
cordate, not coriaceous, with nerves  
not projected, pilose, with appressed,  
eglandular hairs on both surfaces;  
segments 5, in 1 plane, middle seg-  
ment obtriangular, 1.7-5.6 mm wide  
at the base [ratio segment width at  
the base/middle segment length =  
0.19-0.27], 3(4)-lobed in distal half  
[ratio secondary sinus length/mid-  
dle segment length = (0.20)0.22-  
0.26(0.28)]; petioles up to 10 cm long,  
without abscission zone, terete, not  
swollen, not deflexed in age, with  
retrorse, appressed, eglandular hairs  
0.2-0.4 mm long, rarely, with scat-  
tered, patent, glandular hairs 0.3-0.4  
mm; stipules (2.8)3-4(4.2) mm long,  
0.8-1.2 mm wide, lanceolate, free, pa-  
pery, brownish red, with eglandular  
hairs on abaxial surface and on the  
margin,  $\pm$  glabrous adaxially. *Inflores-  
cence* a monochasial cyme; cymules  
1(2)-flowered, solitary [ratio cymule  
length/leaf length = (0.8)1-1.2(1.6)];  
peduncles (5.5)6.5-14.9(23) mm long,  
with retrorse, appressed, eglandu-  
lar hairs 0.2-0.3 mm long; bracteoles  
3-4(4.2) mm long, 0.6-0.9 mm wide,  
linear-lanceolate, opposite; pedicels  
(8.5)9.9-14.6 mm long, with retrorse,  
appressed, eglandular hairs 0.1-0.3

mm long. Flowers actinomorphic. *Sepals* (3.8)4.1-4.5(4.8) mm long, 1.7-2.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.6)1-1.1 mm long [ratio mucro length/sepal length = 0.15-0.28], with  $\pm$  patent, eglandular hairs 0.6-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (3.9)4.3-5.3(5.8) mm long, 1.7-2.6 mm wide, erect-patent, rounded,

without claw, pale pink to purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2-2.9 mm long, lanceolate, unknown color, glabrous on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers 0.3-0.5 mm long, unknown color. *Nectaries* 5,

hemispheric, glabrous. *Gynoecium* 2.2-3.2 mm long, unknown color. *Fruit* 14-16.2 mm long, erect, discharge of seed-ejection type; mericarps 2.5-2.9 mm long, 1.3-1.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.4-0.9 mm long; rostrum 9.5-10.5 mm long, with a narrowed apex 0.7-0.9(1) mm long, not twisted, with antrorse, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 0.9-1.3 mm long, with 5 glabrous lobes. *Seeds* 2-2.1 mm long, 1.2-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 206.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to June.

*Distribution*. This species is endemic to southern Celebes, in Indonesia (Fig. 207).

*Habitat*. Open grassy areas on volcanic rocks; 2500-2600 m.

*Additional specimens examined*. **Indonesia**. CELEBES: Gowa district, G. Bawa Karang, subsidiary to G. Lompobatang, 5°19'S, 119°57'E, 14 Feb. 2000, *Argent & al.* 58 (E, GH); Lompo Batang, Bonthain, 5°21'S, 119°56'E, 1938, *Monod de Froideville* 229 (L).

*Discussion*. *Geranium frigidurbis* is a small herb with more or less elongate, prostrate, branched stems some-

Fig. 207. Distribution of *Geranium frigidurbis*.

times rooting at the nodes. Among the few available collections, the underground parts are poorly represented. Nevertheless, *G. frigidurbis* appears to have a  $\pm$  vertical rootstock with thin roots. *Geranium frigidurbis* has leaves with five segments, each of which is 3-lobed at the apex. The leaf indument consists of short, appressed eglandular hairs regularly covering both surfaces. The stipules are narrowly lanceolate and free, and quite similar to the bracteoles. The indument of the stems, petioles, peduncles, and pedicels consist of short, retrorsely appressed eglandular hairs. On some petioles, scattered, patent glandular hairs were observed. According to Veldkamp & Moerman (1978: 466, 469) *G. frigidurbis* has 1- or 2-flowered cymules, but 2-flowered cymules appear to be the exception (the same is also true of *G. potentilloides*). In the type collection of *G. frigidurbis*, only one of 15 cymules has two flowers and no 2-flowered cymules were seen in any of the other collections. *Geranium frigidurbis* can be distinguished from *G. niuginiense* by quantitative features. *Geranium frigidurbis* has longer stipules, bracteoles, sepal mucro, hairs of the sepals and mericarps, a narrowed rostrum apex, and shorter peduncles and pedicels. In contrast, *G. frigidurbis* can be differentiated from *G. potentilloides* by its longer sepal mucro, hairs on the sepals and mericarps, and narrowed rostrum apex. The leaves of *G. frigidurbis* have the middle segment 3-lobed at the apex while in *G. potentilloides* the middle segment is variable and in many cases has more than three lobes (up to nine). In addition, the leaves of *G. frigidurbis* are usually, but not always, smaller than those of *G. potentilloides*. These traits all show some degree of overlap, however, making the preparation of a key to separate the species difficult. The concurrence of all of these characters, together with geographical isolation, suggests that Veldkamp & Moerman (1978: 469) were correct in separating *G. frigidurbis* as a distinct

species. Carolin (1965: 341) included specimens from Sulawesi, here separated as *G. frigidurbis*, within *G. potentilloides* var. *ardjunense* (here considered to be a species endemic to Java). For more details see the discussion under *G. ardjunense*.

**Discussion.** *Geranium potentilloides* is a small herb with more or less elongated, prostrate to ascending stems rarely rooting at the nodes. The rootstock is vertical and with  $\pm$  fusiform roots. *Geranium potentilloides* has leaves with five segments, which are 3-5(9)-lobed at the apex. The leaf indument consists of short, appressed eglandular hairs uniformly covering both surfaces. The cymules are usually 1-flowered, although exceptionally some 2-flowered cymules occur in predominantly 1-flowered individuals. The indument of the stems, peduncles, pedicels, and sepals is usually composed of short appressed hairs. Some specimens both from Australia and New Zealand show longer, patent hairs. Two collections from New Zealand [*Travers s.n.* (G, L), *van Zanten 1602* (L)] and one from Australia [*Tate s.n.* (AD)] show patent glandular hairs on the stem and inflorescence. Leaf size varies widely in both Australia and New Zealand, but small-leaved plants are more frequent in New Zealand. Indeed, some authors (e.g., Allan 1961: 235) have recognized the New Zealand

plants as a distinct species, *G. microphyllum*. However, as Carolin (1965: 338) pointed out, there is no correlation of leaf size with other features. Webb & al. (1988) accepted both *G. microphyllum* and *G. potentilloides* in their New Zealand flora. According to Webb & al. (1988), *G. potentilloides* is distinguished from *G. microphyllum* by the distinctly alveolate seeds, the pink petals, and the sepals with spreading hairs. I have found, however, that all these features vary in a continuum and independently, which makes difficult the recognition of discrete taxa. Dawson & Beuzenberg (2000: 5) counted the chromosomes of *G. microphyllum* ( $2n = 52-54$ ) and de Lange & al. (2004: 880) those of *G. potentilloides* ( $2n = 112$ ). These studies are based on two and one samples, respectively. It appears interesting to confirm these numbers with more samples and to explore their relation to the morphological variation. Nevertheless, elsewhere in *Geranium* there are species with two or more chromosome numbers. For instance, Van Loon (1984c: 289) found  $2n = 28$  and 42 for *G. macrostylum* and  $2n = 20$  and 40-44 for *G. lucidum*. Two counts of *G. potentilloides* from New Guinea by Borgmann (1964: 149) should be attributed to *G. niuginiense* ( $2n = 36$ ) and *G. hyperacron* ( $2n = 56$ ). Mitchell & al. (2009) analyzed two samples of *G. microphyllum* and one of *G. potentilloides* using ETS and ITS sequences. They appear in an unresolved clade, with *G. sessiliflorum*-*G. traversii* as sister group, which suggests that they are closely related.

Carolin (1965: 336) recognized *G. potentilloides* as a broadly defined species that included three varieties. One of them, var. *ardjunense*, is here considered to be an independent species (for more details see the discussion under *G. ardjunense*). The second one, *G. potentilloides* var. *abditum*, was distinguished by Carolin (1965: 340) by its seeds, which are blackish with deep elongated alveolae somewhat larger than those of the other two varieties. However, a broad range

of variation in the form of the cells of seed-coat has suggested that this feature has little taxonomic value.

De Candolle (1824: 639) stated in the protologue that the original material was collected "in Novâ-Hollandiâ", which appears to be a misprint, as Carolin (1965: 337) pointed out. On the lectotype in the Candolle herbarium "Nova Zelandia" is clearly indicated.

*Geranium graniticola* was described by Carolin (1965: 345) as showing affinities with var. *abditum* because of its similar seed coat. Carolin (1965: 345) emphasized that *G. graniticola* has pedicels and peduncles more or less equal in length, while *G. potentilloides* had short peduncles and relatively long pedicels. This feature is very variable, however, even within the same gathering, which suggests that it is not taxonomically useful.

*Geranium potentilloides* is similar to *G. niuginiense* from New Guinea and *G. frigidurbis* from Sulawesi. For more details see the discussion under those species.

*Discussion.* *Geranium ardjunense* is a prostrate to ascending perennial herb, sometimes rooting at the nodes. The rootstock is vertical, slim, and with thin roots. The indument of *G. ardjunense* consists of short, appressed eglandular hairs. The leaves are deeply divided, have five segments, and the lobes are usually 3- or 5-lobed at the apex. *Geranium ardjunense* has 1-flowered cymules, relatively wide bracteoles, and long sepals. The sepals are ca. 5.4-6.5 mm long in flower and enlarge considerably in fruit, reaching 7.9 mm in length. *Geranium ardjunense* is probably the most distinct among the group of species close to *G. potentilloides* (which includes also *G. frigidurbis* and *G. niuginiense*). *Geranium ardjunense* is easily recognized at first sight by its long sepals. Its deeply divided leaves and its wide bracteoles also unequivocally characterize it. Geographically, the nearest species of this group is *G. frigidurbis*, endemic to Sulawesi (around 800 km to the northeast). The latter has less divided leaves, usually with the segments 3-lobed at the apex, shorter stipules, peduncles, pedicels and fruits, narrower bracteoles, and sepals (3.8)4.1-4.5(4.8) mm long. *Geranium homeanum* is more or less sympatric with *G. ardjunense* in central Java. The former, however, is restricted to lower altitudes and is probably adventive. *Geranium homeanum* is easily distinguished by its longer leaves with more lobed segments, its cymules usually 2-flowered, its narrow bracteoles, its shorter sepals and its fruit without a narrowed apex. Reports of *Geranium ardjunense* outside Java refer to other species. Lam (1945: 579) recorded *G. ardjunense* in Sulawesi on the base of two collec-

tions: *Froideville* 229 and *Bünnemeyer* 11906. Carolin (1965: 341) treated *G. ardjunense* as a variety of *G. potentilloides* and included there both collections. Finally, Veldkamp & Moerman (1978: 469) considered those plants to be a distinct species endemic to Sulawesi, which they named *G. frigidurbis*. Carolin (1965: 336) also recorded var. *ardjunense* from Sumatra and Timor. Veldkamp & Moerman (1978: 466-469), however, re-identified the plants from Sumatra and Timor as *G. nepalense* and *G. homeanum*, respectively.

*Perennial herbs*, 20-90 cm tall. *Rootstock* 3-7.4 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with  $\pm$  thickened roots.

*Stem* prostrate to ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with  $\pm$  retrorse, usually appressed, eglandular hairs 0.3-0.9 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae (1.5)2.6-4.1(6.1) cm long, 2.2-8.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.74)0.77-0.82(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (1.6)3.7-6.9(8.3) mm wide at the base [ratio segment width at the base/middle segment length = 0.11-0.29], (3)5-7(9)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.20-0.28(0.35)]; petioles up to 18 cm long, without abscission zone, terete, not swollen, not deflexed in age, with  $\pm$  retrorse, usually appressed, eglandular hairs 0.1-0.8 mm long; stipules 3.2-7.3 mm long, 0.6-1.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary [ratio cymule length/leaf length = (0.5)0.6-1.5(1.9)]; peduncles (8)21.3-47.3(105) mm long, with  $\pm$  retrorse, usually appressed, eglandular hairs 0.2-0.8 mm long; bracteoles 2.6-4.2 mm long, 0.3-0.8 mm wide, lanceolate, whorled; pedicels (8.3)10-19(22.4) mm long, with  $\pm$  retrorse, usually appressed, eglandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* (2.8)3.5-4.2(5.7) mm long, 1.5-2.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.7)0.8-1(1.4) mm long [ratio mucro length/sepal length = 0.17-0.37], with  $\pm$  patent, scattered, appressed, eglandular hairs 0.3-0.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (2.8)3.3-4.7(7.8) mm long, 1.1-3.9 mm wide, erect-patent, rounded, without claw, white or pale pink, glabrous on both surfaces, with

scattered hairs on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.7-3.6 mm long, lanceolate, yellow, glabrous or with scattered hairs 0.1-0.3 mm long on the abaxial surface and margin; anthers 0.3-0.7 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.3-4.7 mm long, yellow. *Fruit* 12.4-18.4 mm long, erect, discharge of seed-ejection type; mericarps 1.8-3.1 mm long, 1.1-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.9 mm long; rostrum 7.5-13 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.5 mm long; stigmatic remnants 0.7-1.3 mm long, with 5 hairy lobes. *Seeds* 1.6-2.3 mm long, 0.9-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 213.

*Pollen*. Ornamentation not studied. *Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges through southeastern Australia (Queensland, New South Wales, South Australia and Victoria) and Tasmania and it is probably introduced in New Zealand, Timor, Java and Hawaii (Fig. 214).

*Habitat*. Disturbed open areas, dunes, grassy slopes, base of cliffs, rock outcrops, temperate rain forests, and *Eucalyptus* L'Hér., *Casuarina* L., and *Acacia* Mill. forests; 0-2700 m.

*Representative specimens examined*.

**Discussion.** *Geranium homeanum* is a prostrate to ascending perennial herb. The stem is usually branched from the base, and there is no evidence that it roots at the nodes. In well-developed plants the rootstock is short, usually vertical, ± branched, not turnip-shaped, and has ± fusiform roots. However, young plants sometimes have a single, ± thickened, tapering rootstock or taproot which is never napiform as in *G. solanderi* or *G. retrorsum*. Carolin (1965: 346) suggested that *G. homeanum* can be annual, probably on the basis of very young plants with a tapering rootstock not yet thickened. *Geranium homeanum* has scattered, short, usually retrorse, ± appressed eglandular hairs. The leaves have five segments, which are usually 5- or 7-lobed at the apex. Leaves with a 3-lobed or 9-lobed middle segment are occasional on sheets in which most leaves have 5- or 7-lobed middle segments. The cymules are usually 2-flowered, although exceptionally some individuals may have a few 1-flowered cymules mixed with the 2-flowered cymules. The sepals are useful for distinguishing *G. homeanum* from other species because they are short, with a proportionally long mucro and with scattered hairs.

A collection from Awarua Bay [Powell *s.n.* (AD)], New Zealand, has sepals like those of *G. homeanum* (short and with long mucro), but no rootstock. More collections should be made in this area to confirm the

Fig. 214. Distribution of *Geranium homeanum*.

presence of *G. homeanum* on New Zealand's South Island. Specimens from Timor have slightly longer sepals, and are more densely hairy. The specimen *De Voogd* 2272 (L) has some glandular hairs on the petioles and pedicels, but duplicates of this collection at BO and NY lack this feature. Otherwise, the plants of this collection fall well within the range of variability of *G. homeanum*. Timor plants were recorded as *Geranium affine* (a synonym for *G. arnotianum*) by J. Britten (Forbes 1885: 501) and as *G. potentilloides* var. *ardjunense* by Carolin (1965: 336). Veldkamp & Moerman (1978: 466-469) rightly re-identified these specimens as *G. homeanum*. Some specimens of *G. nepalense* with predominantly 2-flowered cymules may be difficult to separate from *G. homeanum*. The latter has shorter sepals with a relatively longer sepal mucro, shorter petals, shorter staminal filaments, and a fruit without the rostrum narrowed at the apex. Similarly, in some cases *G. homeanum* can be difficult to distinguish from *G. potentilloides*. Normally, the first species has 2-flowered cymules while the second has predominantly 1-flowered cymules. Exceptions can be found, however. Thus, on some fragmentary herbarium specimens this feature alone may not be sufficient for reliable identification. These cases may be resolved because *G. homeanum* has a longer sepal mucro than *G. potentilloides*. *Geranium retrorsum* and *G. solanderi* are easily distinguished from *G. homeanum* by their turnip-shaped rootstocks. Both *G. retrorsum* and *G. solanderi* have a shorter sepal mucro and more deeply divided leaves than does *G. homeanum* (and *G. solanderi* differs further in having patent hairs on the peduncles and pedicels).

Hanks & Small (1907: 10) reported *G. glabratum* (a synonym for *G. homeanum*) from California (U.S.A.). According to Aedo (2001b: 32) it was considered to be based on confusion with *G. retrorsum*. Later, Aedo (2012: 391) corrected the identification of the Cal-

ifornian plants to *G. core-core*. The status of *G. homeanum* in New Zealand is controversial. According to Gardner (1984: 127) *G. homeanum* is adventive in New Zealand, as evidenced by its preference for modified habitats and the absence of old collections from the North Island. In contrast, Webb & al. (1988: 732) considered this species to be native to New Zealand. Wagner & al. (1990: 732) considered *G. homeanum* not to be native in Hawaii, probably for similar reasons. Carolin (1965: 347) indicated that *G. homeanum* is not native in Java. On the contrary, in southeastern Australia *G. homeanum* occurs in more natural habitats, suggesting that this is the only area to which it is native. Such a hypothesis appears to be more reasonable than the supposition that the species is scattered throughout all the islands and is native to them all. According to de Lange (*in litt.*) *G. homeanum* was introduced by tourists in the Cook Islands, New Zealand. Unfortunately, I was unable to examine a voucher for this report.

**76. *Geranium traversii*** Hook. f., Handb. N. Zeal. Fl. 726. 1867. TYPE LOCALITY: "Chatham Island: waste ground, W. Travers". TYPE: Nez Zealand. Chatham Island, 44°00'S, 176°30'E, W. Travers 25 (lectotype, designated by Carolin 1965: 343, K-000729530!; isoelectotypes, MO!, W!).

*Geranium traversii* var. *elegans* Cockayne, Trans. & Proc. New Zealand Inst. 34: 320. 1902. TYPE LOCALITY: "[Chatham Is]". TYPE: New Zealand. Chatham Island, near summit of Maunganui hill, 43°45'S, 176°35' E, 19 Jan. 1901, L. Cockayne 4342 (lectotype, designated by Aedo 2017a: 135, WELT-30964 image!; isoelectotype, NY-02317715!).

*Perennial herbs*, 20-38 cm tall. *Rootstock* 9-10 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, sericeous, with usual-

ly retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.8 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae (1.6)2-6.1(6.7) cm long, 2.1-7.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.56-0.68], polygonal in outline, base cordate, not coriaceous, with nerves not projected, silky-hairy on both surfaces; segments 5-7, in 1 plane, middle segment obtriangular, 4.2-20.9 mm wide at the base [ratio segment width at the base/middle segment length = 0.27-0.53], 3-5(6)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.56-0.68]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.6 mm long; stipules 3.9-11.4 mm long, 1.4-3.1(4.3) mm wide, lanceolate, free, papery, brownish red, sericeous on abaxial surface, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.5)1-3.2]; peduncles (5)9-21(33) mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.6 mm long; bracteoles 2.3-6.8 mm long, 0.4-1.2 mm wide, linear-lanceolate, opposite; pedicels 7-39.5 mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.6 mm long. Flowers actinomorphic. *Sepals* (5)5.7-7.8(8.4) mm long, 2.3-3.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.6)0.7-1.1(1.3) mm long [ratio mucro length/sepal length = 0.10-0.22], sericeous, with antrorse, appressed, eglandular hairs 0.3-0.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.4)9.4-12.7(15.9) mm long, 4.3-12 mm wide, erect-patent, rounded, with claw 1-2.6 mm long, white or pale pink, with scattered hairs on the base of the adaxial surface, glabrous abaxially surface, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3-4.9 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half,

with hairs 0.1-0.4 mm long; anthers 0.9-1.4 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.1-5.6 mm long, yellow. *Fruit* 16.1-

19.8 mm long, erect, discharge of seed-ejection type; mericarps 3-3.6 mm long, 1.5-1.9 mm wide, without a strand of fibers, not compressed

at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.4-0.7 mm long; rostrum 10.2-13.3 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 1.9-2.6 mm long, with 5 usually hairy lobes. *Seeds* 2.2-2.7 mm long, 1.3-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 215.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 28, 52, 54$ .

*Phenology*. Collected in flower from November to February.

*Distribution*. This species is endemic to Chatham Is., in New Zealand (Fig. 216).

*Habitat*. Steep, north-facing slopes of soil and clay overlying lava and tuff on rocks near the sea; 0-100 m.

*Additional specimens examined*. **New Zealand**. CHATHAM Is.: Chatham Is., cultivated at Dunedin, *Matthews s.n.* (K); cultivated plant from Christchurch, originally from Chatham Is., Nov. 1920, *Petrie s.n.* (MO, NY); N coast of Chatham Is., 43°45'S, 176°37'W, Jan. 1901, *Cockayne 4343* (NY); Chatham Is., bay E of blowhole, S of Cape Young, 43°45'S, 176°30'W, 7 Feb. 1982, *Given & Williams 12799* (AD, MO, MEL, NSW); Chatham Is., 43°45'S, 176°35'W, *Haorbiy s.n.* (W); Chatham Is., 43°45'S, 176°30'W, *Kirk s.n.* (F, GH, MO); Chatham Is., 43°45'S, 176°35'W, 1952, *Lothian s.n.* (AD); Chatham Is., 43°45'S, 176°30'W, 1850, *Sinclair s.n.* (NSW); Chatham Is., 43°56'S, 176°31'W, 1903, *Cox 1694* (K).

Fig. 216. Distribution of *Geranium traversii*.

*Discussion.* *Geranium traversii* is an erect, robust herb well characterized by its shallowly divided leaves with a dense silky indument. The very wide (in some cases almost as wide as long) petals with an evident claw are also distinctive. The petals are usually longer than 9 mm, but shorter petals occur in some, probably re-flowering, individuals. The habit and underground parts of *G. traversii* are not well known because most available sheets have only fragments. The rootstock is  $\pm$  thickened and tapering. Allan (1961: 236) indicated that the stems are “. . . branching, often producing arched runners that root and produce off-set plants.” However, I have not observed this feature among the specimens I have seen. Mitchell & al. (2009) and Heenan & al. (2010) suggested that *G. traversii* is related to *G. brevicaulis* on the basis of ETS and ITS sequence data of the native species from New Zealand.

**77. *Geranium neglectum*** Carolin, Proc. Linn. Soc. New South Wales ser. 2, 89: 343, pl. 6 fig. 12, pl. 7 fig. 8. 1965. TYPE LOCALITY: “Banks of the Boyd River, Jenolan-Kanangra. R. C. Carolin No. 916, 23.3.1959 (NSW 66124)”. TYPE: Australia. New South Wales, Boyd River, Jenolan-Kanangra, 33°49'S, 150°02'E, 23 Mar. 1959, R.C. Carolin 916 (holotype, NSW-66124).

*Perennial herbs*, 34-102(120) cm tall. *Rootstock* 1.5-5.8 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with  $\pm$  thickened roots. *Stem* prostrate to ascending, leafy, usually rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae (1.5)2.2-3.7(5.2) cm long, 2.2-5.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.71)0.78-0.85(0.90)], polygonal in outline, base cordate, not

coriaceous, with nerves not projected,  $\pm$  strigose on adaxial surface and with appressed, eglandular hairs restricted to the nerves abaxially; segments 5, in 1 plane, middle segment obtriangular, 2.4-4.4(5.4) mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.24], (1)3(5)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.06)0.08-0.29(0.33)]; petioles up to 44 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; stipules 2-4.8 mm long, 0.3-0.9 mm wide, lanceolate to subulate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin,  $\pm$  glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1(2)-flowered, solitary [ratio cymule length/leaf length = (1.8)2.3-4.5(6.1)]; peduncles (27)57-93(205) mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; bracteoles 2.3-3.8 mm long, 0.4-0.7 mm wide, linear-lanceolate, opposite; pedicels (20)34-49(57) mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long. Flowers actinomorphic. *Sepals* (5.7)6.2-7.8(8.3) mm long, 2.1-2.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.5)0.6-0.9(1) mm long [ratio mucro length/sepal length = 0.08-0.15], with antrorse, appressed, eglandular hairs 0.1-0.3 mm long on the abaxial surface, glabrous adaxially. *Petals* (9)10.8-13.6(15.6) mm long, 4.8-9.1 mm wide, erect-patent, rounded, without claw, pink with white base, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.4-7.9 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers (1.3)1.4-1.6 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoeceium* 4.9-9.8 mm long, yellow. *Fruit* 21.2-26.5 mm long, erect, discharge of seed-ejection type; mericarps

2.7-3.6 mm long, 1.4-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black, with  $\pm$  patent, eglandular hairs 0.3-0.7 mm long; rostrum 14-18.5 mm long, with a narrowed apex 2-3.8 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants (1.9)2.4-2.7(3.6) mm long, with 5 glabrous lobes. *Seeds* 1.9-2.4 mm long, 1.1-1.4 mm wide, finely reticulate, uniformly colored, dark brown, glabrous. Cotyledons with entire margin. Fig. 217.

*Pollen.* Ornamentation not studied.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from November to May.

*Distribution.* This species ranges from Queensland to Victoria, in southeastern Australia (Fig. 218).

[=Combienbar] Valley (Eastern head of Bemm River), 37°27'S, 148°57'E, 1887, *Merrall s.n.* (MEL); between Bemm and Coombinah [= Combienbar] Rivers, 37°30'S, 148°55'E, 1887, *Sayer s.n.* (MEL).

**Discussion.** *Geranium neglectum* is a prostrate perennial herb, but with the stems ascending when supported by other plants. It has a long, branched stem usually rooting at the nodes. The rootstock is short, branched, not turnip-shaped, and has  $\pm$  fusiform roots. The indument of *G. neglectum* is composed of scattered, short, usually retrorsely appressed hairs. The leaves have five segments, which are usually 3-lobed at the apex. Leaves with an unlobed middle segment are occasional on sheets in which most leaves have 3-lobed middle segments. The stipules are free, narrow, lanceolate, and usually have a subulate apex. The cymules are usually 1-flowered although exceptionally some 2-flowered cymules occur on predominantly 1-flowered individuals. The pedicels and peduncles, as well as the petals, are all noticeably longer than those of other *Geranium* species. The fruit rostrum has a long narrowed apex. *Geranium neglectum* is similar to *G. potentiloides*, but is easily distinguished from the latter species by its longer peduncles, longer petals, and the apex of the rostrum, which is always narrowed and usually longer (2-3.8 mm).

**The Nodosum Group**—This group gathered perennial species with opposite leaves with broad and rhombic to ovate segments, distinct stipules, 2-flowered cymules arranged in dichasial inflorescence, long, narrow and emarginate petals, lanceolate staminal filaments, and glabrous nectaries. Yeo (2002a) recognized an “*Endressii* Group” that is renamed here as the *Nodosum* Group, because *G. endressii* is relocated into the *Sylvaticum* Group. *Geranium endressii* has alternate leaves on the base of the stem which suggests that it is more related to the *Sylvaticum* Group.

**Perennial herbs**, 19-50 cm tall. **Rootstock** 3-6.1 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. **Basal leaves** in a persistent rosette, cauline leaves opposite; leaf laminas (4.3)7.1-9(13.7) cm long, 5.7-17.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.74)0.79-0.84(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  appressed, eglandular hairs on both surfaces; segments (3)5, in 1 plane, middle segment ovate, (8)15-20.3(24.8) mm wide at the base [ratio segment width at the base/middle segment length = 0.22-0.29(0.31)], (9)11-17(21)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.05)0.06-0.09(0.12)]; petioles up to 19 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.7

mm long; stipules 3.9-15.9 mm long, 0.8-3.6 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. **Inflorescence** a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1)1.6-2.1]; peduncles (24)29-61(86) mm long, with eglandular, retrorse, appressed hairs 0.2-0.4 mm long; bracteoles 1.9-12 mm long, 0.5-1.3 mm wide, linear-lanceolate, whorled; pedicels (4.2)12-19(21) mm long, with retrorse, appressed or hook-shaped, eglandular hairs 0.1-0.3 mm long. Flowers actinomorphic. **Sepals** (6.4)6.8-7.7(7.8) mm long, 2.4-3.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.5)1.8-2.3(3.7) mm long [ratio mucro length/sepal length = 0.23-0.47], with antrorse, appressed, eglandular hairs 0.2-0.4 mm long on the abaxial surface, glabrous adaxially. **Petals** (11.1)13.2-16.7(18.6) mm long, (4.8)5.2-6.5(8.4) mm wide, erect-patent, emarginate (notch 1.2-2.4 mm deep), without claw, light pink to deep magenta, hairy on the base of both surfaces, ciliate on the basal margin, with hairs 0.3-0.5 mm long. **Stamens** 10, both whorls bearing anthers; filaments (6.8)8.3-9.3(10.2) mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.5 mm long; anthers (1.5)1.6-1.9(2.1) mm long, blue. Nectaries 5, hemispheric, glabrous. **Gynoeceium** 5.3-9.7 mm long, purple. **Fruit** (24)27-30(32) mm long, erect, discharge of seed-ejection type; mericarps 3.1-4.3 mm long, 1.4-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.2-0.6 mm long; rostrum 16-23 mm long, with a narrowed apex 2.9-5.9 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 3.3-4.7 mm long, with 5 hairy lobes. **Seeds** 2.7-2.8 mm long, 1.7-2 mm wide, reticulate, uniformly

colored, brown, glabrous. Cotyledons with entire margin. Figs. 219, 220.

**Pollen.** *Geranium*-type (Gagnepain 1903: 86; Velasco 1992b: 55).

**Chromosome number.**  $2n = 28$ .

**Phenology.** Collected in flower from April to September.

**Distribution.** This species ranges from northeastern Spain, through southern France, Italy and Switzerland to Slovenia and Croatia and it is introduced in Belgium, Germany and Great Britain (Fig. 221).

**Habitat.** Meadows, streams, edge of *Abies* Mill., and *Fagus* L. forests; 250-1600 m.

June 1930, *Bar s.n.* (MA, P). VALAIS: Valesia, chez les Reuses supra Orsières, 46°1'N, 7°9'E, 12 Aug. 1896, *Bernouilli s.n.* (W).

**Discussion.** *Geranium nodosum* is an erect perennial herb with a thin horizontal rootstock, opposite and shallowly divided leaves, free and narrow lanceolate stipules and long and emarginate petals. Stem-leaves gradually diminish in size and usually reduce the length of the pair of basal segments giving an appearance of 3-segment leaves. In well-developed plants the

inflorescence is arranged in a primary dichasial cyme with two main branches where cymules are disposed monochasially. The indumentum varies in density and consists of short, retrorse, appressed, eglandular hairs distributed on the stem, petioles, peduncles, and pedicels. Sometimes the hairs of pedicels are retrorse and hook-shaped.

*Geranium nodosum* is quite similar to *G. versicolor* in general appearance, shape of leaves, and petals; however, *G. nodosum* never has glandular indumentum, and the eglandular hairs are shorter and retrorse-appressed or hook-shaped (in *G. versicolor* eglandular hairs are longer and patent). Stipules, peduncles, pedicels, and rostrum narrowed apex of the fruit are shorter in *G. nodosum* than in *G. versicolor*, although with some overlap. Additionally, in *G. nodosum* the sepal mucro is longer, petals are light pink to deep magenta, and stigmatic remnants are hairy.

*Geranium nodosum* and *G. versicolor* have an allopatric distribution. The first grows from eastern Pyrenean to northern Balkans, while the second is found in southern Italy and southern Balkans. They appear to overlap in Central Apennines. *Geranium nodosum* is widely used in gardens and naturalized in Great Britain, Belgium, and Germany. Some French lowland localities shown in the map (e.g., Var, Bougon, *Bourgeau s.n.*, P) probably also represent naturalizations.

**Discussion.** *Geranium rectum* is an erect perennial herb with a short horizontal rootstock, opposite and shallowly divided leaves, free and narrow

lanceolate stipules and long petals. The indumentum consists of appressed, eglandular hairs distributed from the stem base to inflorescence. *Geranium rectum* also shows a distinctive indumentum of long, patent glandular hairs ending in a narrow cell (this apical cell is of similar width to

that of the basal cell). These hairs are always present in a variable density, on sepals, and sometimes on stems, petioles, peduncles, and pedicels. As in other species of the genus, such as *G. collinum*, *G. nodosum*, or *G. psilostemon*, the peduncle of the cymules may be noticeably long, especially toward the base of the inflorescence. The petals are narrow, slightly emarginate, and hairy on the basal third of the adaxial surface.

*Geranium rectum* is easily differentiated from *G. nodosum* and *G. versicolor* for its short staminal filaments, its long and distinctive glandular hairs on sepals and pedicels, and its leaves with a rhombic middle segment.

Since Edgeworth & Hooker (1874: 429) recorded *G. rectum* in the Himalayas ("Kashmir, Falconer; in Baltal, T Thomson"), some authors have identified Himalayan specimens as *G. rectum* or have accepted this name in the regional literature (i.e., Nasir 1983; Malhotra 1997). The origin of the mistake may be from some specimens identified as *G. rectum* [Falconer 324 (P-05124324, other duplicates examined are *G. wallichianum*); Duthie s.n. (18 July 1892, WU)] that really belong to *G. rubifolium*. The latter is a species that resembles *G. rectum* by its shallowly divided leaves. Differences between *G. rectum* and *G. rubifolium* are addressed in the discussion of the latter species. All these data strongly suggest that *G. rectum* should be excluded from the Himalayas.

**Discussion.** *Geranium versicolor* is an erect perennial herb, with a medium-length horizontal rootstock, thin roots, opposite and shallowly divided leaves, free and narrow lanceolate stipules, and long petals. The inflorescence is arranged in a primary dichasial cyme with two main branches where cymules are disposed monochasially. Stem-leaves gradually diminish in size and usually reduce the length of the pair of basal segments, giving an appearance of 3-segment leaves. The indumentum consists of spread, eglandular hairs distributed in a variable density from the stem base to inflorescence. Additionally, *G. versicolor* has very short, patent glandular hairs throughout the plant, but more conspicuous and in higher density on peduncles and pedicels. The petals are usually deeply notched, white, and with a close network of fine magenta-colored veins that fade with age (Yeo 2002a: 65). The indumentum of petals is restricted to the base and occurs on both surfaces.

Differences between *Geranium versicolor* and *G. nodosum* are addressed in the discussion of the latter species. *Geranium versicolor* is widely used in gardens and naturalized in Great Britain and France.

**The Arabicum Group**—This group is characterized by the trailing habit, opposite cauline leaves, the broadly ovate and connate stipules, the monochasially branched inflorescence, the petals glabrous or hairy only on the base, and the staminal narrow filaments, without an expanded base. Some relation can be suggested with “The Wallichianum group” on the basis of the trailing habit, opposite leaves, monochasial inflorescence, and connate stipules. The species of “Arabicum group” have, however, shorter flowers that are not dark pigmented.

**Discussion.** *Geranium andringitrense* shares with *G. arabicum* the general appearance, the broadly ovate and connate stipules, and the eglandular indumentum. *Geranium andringitrense* is, consequently, a prostrate herb with a slender vertical rootstock, slim roots, and ascending aerial stems. The aerial stems, however, do not root in the nodes as in *G. arabicum*. The hairs of *G. andringitrense* on the stem, petioles and peduncles and pedicels are always very short and retrorse-appressed. Its stipules are strongly acute, unlike *G. arabicum* that varies from obtuse to acute. The cymules of *G. andringitrense* are predominantly 1-flowered. Some specimens occasionally have 2-flowered cymules, although most of the nodes have 1-flowered cymules. *G. andringitrense* is an endemic from Madagascar, easily recognized from *G. arabicum* by its long sepals and petals. Additionally, *G. andringitrense* further differs from *G. arabicum* in its longer sepal mucro and its longer narrowed apex of the fruit. Although both species coincide in Madagascar the former is found in higher areas.

**82. *Geranium arabicum*** Forssk., Fl. Aegypt.-Arab.: 124. 1775. TYPE LOCALITY: "In Yemen frequens, Arab. Talab vel Châda. Aliis Ghasl" [Talab, Châda, and Ghasl are vernacular names]. TYPE: Yemen. Kurma, 14°34'N, 43°38'E, 1763, *P. Forsskål*

735 (lectotype, designated by Kokwaro 1971a: 647, C-10002309 image!).

**Perennial herbs**, 16-119 cm tall. **Rootstock** 1.6-7.3 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** trailing and ascending, leafy, rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-1.2 mm long. **Basal leaves** in a deciduous rosette, cauline leaves opposite; leaf laminas (1.3)2.6-3.7(6.6) cm long, 1.5-7.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.72)0.81-0.89(0.98)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (1.7)2.6-5.9(11.6) mm wide at the base [ratio segment width at the base/middle segment length = (0.10)0.15-0.25(0.35)], (7)11-15(19)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.16)0.23-0.42(0.58)]; petioles up to 18 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.3 mm long; stipules 3.4-12.3 mm long, 2-5.6 mm wide, broadly ovate (sometimes with a short bifid apex), connate, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 1-2-flowered, solitary [ratio cymule length/leaf length = (0.7)0.9-1.6(2.8)]; peduncles (15)31-58(93) mm long, with retrorse to patent, eglandular hairs 0.2-1 mm long; bracteoles 1.4-4.7 mm long, 0.3-1.4 mm wide, lanceolate, opposite or whorled; pedicels (6.7)15-25(44.3) mm long, with patent to retrorse, eglandular hairs 0.2-1 mm long. Flowers actinomorphic. **Sepals** (3.6)4.8-6.1(7.2) mm long, 1.5-3.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.2)0.5-0.8(1.4) mm long [ratio mucro length/sepal length = 0.05-0.27], with  $\pm$  patent, eglandular hairs 0.3-1.1 mm long, on the abaxial surface, glabrous adaxially. **Petals** (3.9)4.9-8.2(12.4) mm long, (2)2.7-

3.9(7.6) mm wide, erect-patent, rounded or slightly emarginate (notch 0.2-0.7 mm deep), without claw, white to purple, glabrous on both surfaces, with scattered hairs on the basal margin, with hairs 0.1-0.7 mm long. **Stamens** 10, both whorls bearing anthers; filaments (2.1)2.9-3.7(4.5) mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.4 mm long; anthers (0.4)0.6-0.8(1.2) mm long, pink. Nectaries 5, hemispheric, glabrous. **Gynoecium** 2.8-6.9 mm long, pale pink. **Fruit** (12)16-18(24) mm long, erect, discharge of seed-ejection type; mericarps 2.9-4 mm long, 1.2-2 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.8 mm long; rostrum 8.4-16.8 mm long, with a narrowed apex 0.2-1 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.6 mm long; stigmatic remnants 1.1-1.8 mm long, with 5 hairy lobes. **Seeds** 1.9-2.9 mm long, 1.1-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin.

**Pollen.** *Geranium*-type.

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from January to December.

**Distribution.** This species ranges from western Asia (Saudi Arabia and Yemen) to western Africa (Cameroon, Equatorial Guinea and Nigeria) and eastern Africa (Burundi, Eritrea, Ethiopia, Kenya, Madagascar, Malawi, Rwanda, Tanzania, Uganda, Zaire and Zimbabwe).

**Habitat.** Roadsides, disturbed areas, rocky outcrops, grassy slopes, meadows, bamboo formations, bushlands, shady ravines, and forest edges; 700-4000 m.

1. Leaves shallowly divided [ratio main-sinus length/main segment length = (0.72)0.76-0.81(0.88); ratio secondary sinus length/main segment length = (0.16)0.20-0.25(0.33)].

**82a.** subsp. **arabicum**

1. Leaves deeply divided [ratio main-sinus length/main segment length = (0.80)0.87-0.91(0.98); ratio secondary sinus length/main segment length = (0.22)0.30-0.44(0.58)].

*Discussion*. *Geranium arabicum* is a trailing herb with a slender vertical rootstock that has slim roots. The aerial stems are profusely branched and scrambling and rooting in the nodes. This species is easily distinguished by its broadly ovate, connate stipules, present in all nodes of the stem. These stipules may be obtuse or acute, and then sometimes with the tip remaining free. The indumentum varies in density and always consists of short, eglandular hairs. Normally, at least some cymules in each plant of *G. arabicum* are 2-flowered, but 1-flowered cymules are not infrequent. In extreme forms, 2-flowered cymules can be difficult to locate. The petals are usually a little longer than the sepals but widespread throughout the area of *G. arabicum* specimens appear with petals twice as long (up to ca. 10 mm long). One collection from the Aberdare Mountains in Kenya [Strid 2187 (GB, UPS)] has unusual petals of 12.4 mm long, but otherwise it falls into the variability of *G. arabicum*. The petals also vary in color from white to purple, but independent of other features.

The leaves are opposite and very variable in size and degree of division. Scattered throughout the distribution area of the typical *G. arabi-*

*cum*, some forms with deeply divided leaves have been found. These forms lack a particular habitat or area of distribution and are connected by intermediate individuals that, at first, do not advise its taxonomic recognition. I finally have accepted them as subsp. *latistipulatum* because they seem to remain constant in the populations, considering the series of duplicates examined. In these plants, the primary and secondary segments are narrower and more deeply divided than in those of *G. arabicum* s.str. There is some overlap in all measurements that difficult identifications and no other feature has been found to support this subspecies.

Gilbert & Vorster (2000: 366) proposed a “*G. sp.* = *Miehe* 3002” and a “subsp. = *Ash* 1711”, both without Latin description nor holotype. I have seen one herbarium sheet from “Bale Mountains National Park, Sanetti Plateau, E of Mt Batu, between Tulu Dimtu and Garba Guracha” collected by Friis & al. 5750 (C) that could correspond to the former and that I have classified as *G. kilimandscharicum* and a dupla of *Ash* 1711 (MO) that I have classified as *G. arabicum* subsp. *latistipulatum*. This provisional way of describing species that is seen in some floras is somewhat disappointing as it makes it difficult to analyze the variability of the species concerned.

Wondimu & al. (2017) studied the complex of *G. arabicum* and allied species of mainland Africa using AFLP markers. They focused the work on alpine populations and they identify only two genetic groups corresponding to *G. arabicum* and *G. kilimandscharicum*. These authors considered that some taxa not validly described by Gilbert & Vorster (2000), as well as subsp. *latistipulatum* do not deserve taxonomic recognition.

According to Hilliard & Burt (1985: 222), *G. arabicum* is also present in South Africa (Eastern Cape, Port St. Johns, 31°37'S, 29°32'E, Wager s.n. (PRE)). Unfortunately, it has not been possible to examine any voucher of that record.

### 83. *Geranium kilimandscharicum*

Engl., Abh. Königl. Akad. Wiss. Berlin 1891(2): 274. 1892. TYPE LOCALITY: “Kilimandscharo, auf den oberen Grasflächen von 4000-4500 m (blühend im November -- Dr. Hans Meyer n. 16, 255)”. TYPE: Tanzania. Kilimandscharo, Nov., H. Meyer 16, 255 (B destroyed). Tanzania. Kilimanjaro, near Peters Hut, 3°08'S, 37°26'E, 16 June 1948, O. Hedberg 1221 (neotype, designated by Kokwaro 1971b: 8, UPS-139989; isotypes, EA, K!, SI!).

*Perennial herbs*, 4-19 cm tall. *Rootstock* 1.4-3.6 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.1-0.7 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae (0.9)1.1-1.7(2.4) cm long, 1.1-2.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.69)0.70-0.74(0.81)], orbicular in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, (1.7)1.8-2.7(5.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.24)0.27-0.33(0.44)], 3-5(7)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.22)0.28-0.36(0.49)]; petioles up to 7 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.2-0.5 mm long; stipules 1.9-4.2 mm long, 1.9-3.8 mm wide, broadly ovate, connate, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.5)0.6-1.2(1.9)]; peduncles (2.2)7-22(30) mm long, with retrorse to patent, eglandular hairs 0.1-0.4 mm long; bracteoles 2.1-4.6

mm long, 0.6-2.5 mm wide, lanceolate, opposite; pedicels (1.8)7.9-14.9(17.3) mm long, with patent to retrorse, eglandular hairs 0.1-0.5 mm long. Flowers actinomorphic. *Sepals* (3.9)4.8-5.9(7.6) mm long, 1.8-3.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.2)0.2-0.5(0.6) mm long [ratio mucro length/sepal length = 0.04-0.12], with ± patent, eglandular hairs 0.2-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.2)5.5-8.3(9.9) mm long, (2.1)2.9-4(4.6) mm wide, erect-patent, rounded, without claw, pale pink or white, glabrous. *Stamens* 10, both whorls bearing anthers; filaments (2.4)2.6-3.3(3.5) mm long, lanceolate, white, glabrous or pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers (0.7)0.7-0.8(0.9) mm long, pink. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.9-4.1 mm long, white. *Fruit* (13)14.9-16.9(18) mm long, erect, discharge of seed-ejection type; mericarps 2.5-3.3 mm long, 1.5-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.2-0.4 mm long; rostrum 9.5-12.8 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 0.9-1.9 mm long, with 5 glabrous lobes. *Seeds* 2-2.2 mm long, 1.4-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 232, 233.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 431).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from Ethiopia through Uganda and Kenya to northern Tanzania (Fig. 234).

*Habitat*. Disturbed areas, grassy slopes, rocky outcrops, bogs and ericaceous scrubs; 2900-4250 m.

*Additional specimens examined*. **Ethiopia**. OROMIA: Bale Region, Bale Mountains

**Discussion.** *Geranium kilimandscharicum* is an herb with a slender vertical rootstock and prostrate aerial stems that do not root in the nodes as in *G. arabicum*. The former shares with *G. arabicum* the general appearance, the broadly ovate and connate stipules, and the eglandular indumentum. The stipules of *G. kilimandscharicum* are shorter than in *G. arabi-*

*cum* and always with a rounded apex. The inflorescence is monochasially branched with cymules shorter than those of *G. arabicum* and constantly 1-flowered. The fruit of *G. kilimandscharicum* is a bit shorter than that of the *G. arabicum* and has a rostrum without a narrowed apex and glabrous stigmatic remnants. The leaves of *G. kilimandscharicum* are small and

frequently red on the abaxial surface. They are orbicular in outline and with the middle segment obtriangular, in contrast with *G. arabicum* that has leaves pentagonal in outline and with the middle segment rhombic. The number of lobes of the middle segment is also a good difference among both species, being 3-5(7) in *G. kilimandscharicum* and (7)11-15(19) in *G. arabicum*.

*Geranium kilimandscharicum* occurs at higher altitudes than *G. arabicum*. As Kokwaro (1971b) indicated some specimens of the contact area between both species are sometimes difficult to identify.

8.1(8.5) mm long, lanceolate, pink, covered densely with hairs 0.4-1 mm long on the abaxial surface and margin, hairless towards the tip; anthers (1.4)1.5-2(2.2) mm long, unknown color. Nectaries 5, hemispheric, usually with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 5.8-8.4 mm long, purple. *Fruit* 18.9-25(27.6) mm long, erect, discharge of seed-ejection type; mericarps 3-3.6 mm long, 1.3-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.5 mm long and, sometimes, with  $\pm$  patent, glandular hairs 0.1-0.2 mm long; rostrum 11.1-17.9 mm long, with a narrowed apex 1.2-3.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.7 mm long and, occasionally, scattered  $\pm$  patent, glandular hairs 0.5-1 mm long; stigmatic remnants 3-4.5 mm long, with 5 glabrous lobes. *Seeds* 2.4-3.2 mm long, 1.2-2.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 235.

*Pollen*. *Geranium*-type (Tan & al. 1996: 212).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to December.

*Distribution*. This species ranges from southeastern China (Guizhou, Hubei, Sichuan, Yunnan) to northern Thailand (Fig. 236).

*Habitat*. Limestone ridges and forest edges; ca. 2100 m.

*Additional specimens examined*. **China**. GUIZHOU: Kouy-Tchéou, 26°38'N, 106°37'E, *Cavalerie* 2952 (MA, P). *Discussion*. *Geranium franchetii* is an erect herb, well characterized by its cauline alternate leaves and short rootstock, along which are thickened roots. It has erect-patent petals hairy on 1/4-1/2 of their adaxial surface and on the base of the abaxial one and staminal filaments with long hairs. The nectary indumentum is variable but usually has a tuft of hairs at the top. The stipules may be free or connate, at least at some nodes of the plant; this feature varies even within the same specimen. Among the studied specimens, no material with glandular hairs was observed, except by some scattered hairs on the fruit.

*Geranium siamense* is only known from the type. It lacks the rootstock, and has sepals and fruit a bit longer than *G. franchetii*, occasionally with scattered glandular hairs, but otherwise it falls into the variability of *G. franchetii*.

Although *G. franchetii* has alternate leaves on the stem and staminal filaments with a narrow base, similar to the species of the *Sylvaticum Group*, it cannot be ascribed to this group due to its hairy petals and the presence of connate stipules. This seems to be an isolated species with no obvious resemblance to other *Geranium*.

**85. *Geranium psilostemon*** Ledeb., Fl. Ross. 1(2): 465. 1842. TYPE LOCALITY: "Hab. in provinciis caucasicis occidentibus! (Nordmann)". TYPE: Georgia. Caucasus, Adshara, 41°40'N, 42°00'E, *A. Nordmann s.n.* (lectotype, designated by Novoselova 1998: 149, LE!).

**Discussion.** *Geranium psilostemon* is an erect perennial herb with thickened roots along a short horizontal rootstock, opposite and shallowly divided leaves, free stipules, and long petals. The indumentum consists of appressed, eglandular hairs. At the pedicels, sepals, and fruits there are also patent glandular hairs that occasionally appear on peduncles. The inflorescence is dichasially arranged. The peduncle of the cymules is noticeably long toward the base of the inflorescence. The sepals have five nerves and a long mucro. The petals are ciliate on the basal margin and have a distinctive dark spot at the base that reaches about a fourth of their length. The staminal filament apex, the anthers and the stigmas are blackish, as is the petal base.

The affinities of *G. psilostemon* appear obscure. Yeo (2002a: 67) included *G. psilostemon* in the *Sylvaticum Group*. It, however, lacks some important features of this group, such as the alternate leaves on the middle part of the stem and the aggregates of cymules at the top of each branch. The structure of the inflorescence of *G. psilostemon* and the leaf arrangement suggest that it is more similar to the *Pratense Group*.

Fig. 238. *Geranium psilostemon* (Based on: Aedo 10452, MA).

Fig. 239. Distribution of *Geranium psilostemon*.

(including *G. collinum*). However, *G. psi-lostemon* has glabrous nectaries and lacks the typical staminal filaments of the *Pratense Group*, with a broad triangular base abruptly narrowed toward the apex.

The chromosome number  $2n = 26$  attributed to this species (Martin & al. 2022) should be confirmed. According to Bobrov (1949: 18), this species is also present in North Caucasus (Dagestan, near Durushtal in former Kyurin district, 41°45'N, 47°44'E). Unfortunately, it has not been possible to examine any voucher of that record.

*Perennial herbs*, 21-80 cm tall. *Rootstock* 5.2-14 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, with napiform roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.1-1.6 mm long. *Basal leaves* in a  $\pm$  deciduous rosette, cauline leaves opposite; leaf laminas (2.5)3.3-7.1(9.6) cm long, 3.4-13.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.71)0.78-0.81(0.87)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (3.1)5.5-11.8(17.4) mm wide at the base [ratio segment width at the base/middle segment length = (0.14)0.21-

0.25(0.29)], (7)9-11(16)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.16)0.19-0.31(0.43)]; petioles up to 33 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.4 mm long; stipules 3.5-10.1 mm long, 2.2-5.6 mm wide, broadly lanceolate, connate (at least at the base), papery, brown, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.5)2.4-3(4.3)]; peduncles (16)35-72(158) mm long, with patent to retrorse, eglandular hairs 0.2-1.2 mm long; bracteoles 2.3-10.6 mm long, 0.5-3.5 mm wide, lanceolate, rarely ovate, whorled; pedicels (6.6)14-23(44) mm long, with patent to retrorse, eglandular hairs 0.1-1.1 mm long. Flowers actinomorphic. *Sepals* (6.3)6.5-8.1(9) mm long, 2.2-3.8 mm wide, lanceolate, smooth, not accrescent, nerves (3)5, mucro (0.7)1-1.4(3.2) mm long [ratio mucro length/sepal length = 0.12-0.49], with antrorse to patent, eglandular hairs 0.1-1.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (10.1)11.7-13.4(15.7) mm long, (3.5)5.4-7.1(10.7) mm wide, erect-patent, rounded, without claw, pink to purple, hairy on the basal 1/3-1/2 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.6-1.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.2)6.6-8.3(9.9) mm long, lanceolate, pink, covered densely with hairs 0.3-2 mm long on the abaxial surface and margin, hairless towards the tip; anthers (1.6)1.7-2.3(2.4) mm long, purple. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6-9.1 mm long, purple. *Fruit* (18.7)20.1-23.4(23.8) mm long, erect, discharge of seed-ejection type; mericarps 2.6-3.8 mm long, 1.5-1.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosus, without a basal prong, brown,

with  $\pm$  patent, eglandular hairs 0.2-1 mm long; rostrum 11.3-15 mm long, with a narrowed apex 2-3.2 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long; stigmatic remnants (2.3)2.8-4.6(5) mm long, with 5 usually glabrous lobes. Seeds 1.8-2.8 mm long, 0.9-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 240.

*Pollen.* *Geranium*-type (Park & Kim 1997: 313 [sub *G. henryi*]; Tan & al. 1996: 212 [sub *G. butoense*]).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from March to October.

*Distribution.* This species ranges from western Burma to central China (Guizhou, Henan, Hubei, Shaanxi, Shanxi, Sichuan and Yunnan) (Fig. 241).

*Habitat.* Meadows, grassy slopes and forest edges; 600-4100 m.

**Discussion.** *Geranium rosthornii* is an erect herb with connate stipules and opposite leaves. It has erect-pat-

ent petals hairy on one-third to one-half of their adaxial surface and on the base of the abaxial one and staminal filaments with long hairs. Some specimens have noticeably broad bracteoles, but otherwise they agree with *G. rosthornii*. This species resembles some specimens of *Geranium dahuricum*, although it can be distinguished by its usually short napiform roots along the rootstock (not long and fasciculate), its leaves with a broad middle segment, its longer stipules, and its denser indumentum on petals and staminal filaments.

The type of *G. bockii* has leaf blades with segments more rhombic than those of *G. rosthornii*; otherwise they are undistinguishable. It is mentioned in the original protologue that *G. pseudofarreri* may have glandular hairs, which has not been observed in any specimen of *G. rosthornii*. Unfortunately, the original material of the former is not available and, consequently, its synonymization remains provisional.

**Discussion.** *Geranium rotundifolium* is an annual species readily identified by the entire petals, the fruit with smooth mericarps and the reticulate seeds. It is native throughout Europe, northern Africa, and central and western Asia and has been introduced in many parts of America (Aedo 2012), South Africa and Australia (Aedo 2017a). Täckholm & Chrtek (1968: 141) indicated this species in Egypt. Unfortunately, it has not been possible to study any herbarium voucher of such record. *Geranium rotundifolium* has been frequently confused with *G. pusillum* and *G. molle*, both of which have carpel-projection fruit discharge (subg. *Robertium*). *Geranium molle* has petals emarginate at the apex and mericarps transversely wrinkled and glabrous, while in *G. rotundifolium* the petals are rounded at the apex and the mericarps are smooth and covered with patent hairs. *Geranium pusillum* has slightly emarginate petal apices, smooth mericarps with appressed hairs, and a rostrum without a narrowed apex. The chromosome number  $2n = 28$  attributed to this species (Martin & al. 2022) should be confirmed.

Yeo (2002a: 66) included *G. rotundifolium* in the monotypic "Rotundifo-

lium Group", showing the difficulties to establish affinities with other species of the genus. *Geranium rotundifolium* seems to be a very isolated species that is difficult to relate to other living species of *Geranium*.

*Perennial herbs*, 18-81 cm tall. *Rootstock* 1.6-9.5 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.3-0.8 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves alternate (1-2) and upper opposite; leaf laminas (2.6)5.6-9.1(13) cm long, 3.2-15.5 cm wide, not peltate,

palmatifid [ratio main-sinus length/middle segment length = (0.62)0.76-0.82(0.84)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (5.2)11.4-16.1(22.7) mm wide at the base [ratio segment width at the base/middle segment length = (0.16)0.20-0.27(0.44)], (9)12-28(33)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.08)0.10-0.16(0.22)]; petioles up to 26 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, ± appressed, eglandular hairs 0.3-0.9 mm long; stipules 1.8-11.6 mm long, 0.9-5.7 mm wide, lanceolate, free or partially connate, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.5)1.7-8.5(9.5)]; peduncles (36)48-105(155) mm long, with retrorse to patent, eglandular hairs 0.2-0.5 mm long and, usually, patent, glandular hairs 0.7-1.3 mm long; bracteoles 2.1-8.7 mm long, 0.4-1.2 mm wide, lanceolate, whorled; pedicels (12)23-35(39) mm long, with patent, eglandular hairs 0.2-0.5 mm long and, usually, patent, glandular hairs 0.5-2.1 mm long. Flowers actinomorphic. *Sepals* (6)7.2-8.5(9.5) mm long, 2.2-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.2)1.8-3.4(3.5) mm long [ratio mucro length/sepal length = 0.19-0.48], with ± patent, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.9-2 mm long on the abaxial surface, glabrous adaxially.

*Petals* (14.1)16.6-18.2(27) mm long, (7.7)9.5-13.8(18.4) mm wide, erect-patent, emarginate (notch 0.5-1.4 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-0.9 mm long. *Stamens* 10, both whorls bearing anthers; filaments (4.7)5.1-6.6(8.9) mm long, lanceolate, purple, pilose

on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.6 mm long; anthers (1.3)1.7-2.1(2.3) mm long, purple. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6-11.9 mm long, dark purple. *Fruit* (28)30-32(35) mm long, reflexed when immature, discharge of seed-ejection type; mericarps 3.3-4.8 mm long, 1.8-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at the apex), without basal beak, with a basal callosus, without a basal prong, brown, with ± patent, eglandular hairs 0.4-0.8 mm long and, patent, glandular hairs 0.5-1.6 mm long; rostrum 20-27 mm long, with a narrowed apex 1.1-2.4 mm long, not twisted, with ± patent, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.7-1 mm long; stigmatic remnants 3-4.2 mm long, with 5 glabrous lobes. *Seeds* 2.9-3.5 mm long, 1.7-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 245.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to August.

*Distribution*. This species ranges from northern Pakistan to northwestern India (Himachal Pradesh and Jammu-Kashmir) (Fig. 246).

*Habitat*. Conifer forest edges; 2300-3600 m.

*Additional specimens examined*. **India**. HIMACHAL PRADESH: Dalhousie, Punjab, 32°31'N, 75°58'E, 12 July 1936, Koelz 8883 (GH). **Discussion.** *Geranium rubifolium* is an erect herb with a long and slim, horizontal rootstock that has slender roots. The basal internodes of the stem are short and usually with 1-2 alternate leaves. The inflorescence is monochasially arranged, with 2-flowered cymes on the upper nodes of the stem, which bear opposite leaves. The indumentum consists of eglandular and glandular hairs, the latter show some variation in density and are usually copious on pedicels and sepals. The stipules may be free or connate but with the tip remaining free. Both types can be found on the same individual. The stigmas remain dark purple in herbarium specimens.

The affinities of *G. rubifolium* appear obscure. Yeo (2002a: 95) included this species in the *Wallichianum* Group, probably because of the stigma color. *Geranium rubifolium*, however, differs from this group in its alternate leaves on the basal nodes, and its clear staminal filaments and anthers. *Geranium rubifolium* resembles *G. schmidii*, a Himalayan species of the *Sylvaticum* Group because both

Fig. 245. *Geranium rubifolium*. a. Habit. b. Leaf. c, d. Stipules. e. Bracteoles. f. Sepals. g. Petal. h. Flower without petals and sepals. i. Stamen. j. Fruit. k. Mericarp. l. Seed. Fig. 246. Distribution of *Geranium rubifolium*.

have long and emarginate petals. Nevertheless, the species of the latter group has a dichasially arranged inflorescence with aggregates of cymules toward the apex of each branch, free stipules, and glabrous nectaries. Additionally, *G. rubifolium* further differs from *G. schmidii* in its less deeply divided leaves, its reflexed fruits, and its shorter narrowed apex of the fruit.

*Geranium rubifolium* has sometimes been confused with *G. rectum*, a species of the *Nodosum* Group that grows on the Tien Shan Mountains, with shallowly divided leaves. The latter species has shorter sepals and petals, glabrous nectaries, erect fruits, dichasial inflorescences, and opposite leaves with free stipules.

According to art. 9.12 of the Shenzhen Code the lectotype of *G. rubifolium* has been chosen on the illustration cited by Lindley (1840), since no other original material has been located. An epitype is also designated for purposes of the precise application of the name.

*Perennial herbs*, 21-60 cm tall. *Rootstock* 5.9-14 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.7-3.1 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminae (2.3)3.1-4(5.1) cm long, 3-5.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.79)0.83-0.87(0.90)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic (with lanceolate lobes), (1.2)2.5-3.1(5.5) mm wide at the base [ratio segment width at the base/

middle segment length = (0.06)0.11-0.14(0.17)], 3-5(7)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.27)0.31-0.39(0.48)]; petioles up to 8 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.6-2.3 mm long; stipules 2.5-5.8 mm long, 1.6-4.4 mm wide, lanceolate, free or connate at the base, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (1.9)2.4-3.2(3.3)]; peduncles (25)44-80(96) mm long, with patent, eglandular hairs 0.5-2.3 mm long; bracteoles 1.8-3.8 mm long, 0.7-1.6 mm wide, lanceolate, opposite; pedicels (15)21-37(53) mm long, with patent, eglandular hairs 0.8-2.3 mm long. Flowers actinomorphic. *Sepals* (7.1)8-8.7(11.7) mm long, 3.3-5.2 mm wide, lanceolate, smooth, not accrescent, nerves (3)5, mucro (1.1)1.7-2.3(2.4) mm long [ratio mucro length/sepal length = 0.14-0.34], with patent, eglandular hairs 1-3.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (13.6)15-17.7(21.8) mm long, (8)11.2-14.5(16) mm wide, erect-patent, emarginate (notch 0.6-3 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.5-1.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.4)5.6-8.4(9.1) mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.9 mm long; anthers (1.3)1.7-2.7(2.8) mm long, blue. Nectaries 5, hemispheric, glabrous. *Gynoecium* 6.5-8.8 mm long, purple. *Fruit* (27.9)32-40(41.9) mm long, erect, discharge of seed-ejection type; mericarps 3.7-5.5 mm long, 1.4-2.7 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 2-3 transverse veins at apex), without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.2-2.1 mm long (mainly at the

top of the mericarp); rostrum 19-32 mm long, with a narrowed apex 1.7-3.3 mm long, not twisted, with ± patent, eglandular hairs 0.4-1 mm long; stigmatic remnants 3.3-4.4 mm long, with 5 sometimes hairy lobes. *Seeds* 3.3-4.1 mm long, 2-2.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 247, 248.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 429; Gagnepain 1903: 86; Velasco 1992b: 55).

*Chromosome number*.  $2n = 52?$ ,  $56?$ ,  $82?$ ,  $84$ .

*Phenology*. Collected in flower from April to September.

*Distribution*. This species ranges through Europe to Turkey and the Caucasus and it is introduced in northeastern U.S.A. (Fig. 249).

*Habitat*. Roadsides, meadows, waste grounds, rocky outcrops, shrubby slopes and edge of *Fagus* L., *Picea* A. Dietr., *Pinus* L. and *Quercus* L. forests; 0-2100 m.

#### *Representative specimens examined.*

*Discussion.* *Geranium sanguineum* is easily differentiated from other species of *Geranium* present in Eur-

asia by its 1-flowered cymules, long petals, and its distinctive leaf shape. The leaves are opposite and deeply divided, with leaf segments that usually have three narrow and long lobes. The rootstock of *G. sanguineum* is horizontal, long and robust and has thickened roots along it. The stipules can be free or partially connate at their base. The indumentum consists of long, patent, eglandular hairs that are widespread in varying density throughout the whole plant. Lewis (1969) analyzed the variation in both leaf dissection and size of *G. sanguineum* and associated more dissected or narrower leaves with dry habitats.

As stated in Aedo (2012: 414) *G. sanguineum* has some superficial resemblance with several Mexican spe-

cies. Yeo (2002a: 114) indicated that it has much in common with the *Krameri Group* except for the lack of hairs over the adaxial surface of the petals. Thus Yeo (2002a: 114) suggested the possibility of an affinity to the *Palustre Group*, but without further support. In fact, *G. sanguineum* seems to be a very isolated species that is difficult to relate to other living species of *Geranium*.

According to Van Loon (1984b: 271) the chromosome numbers different to  $2n = 84$  attributed to this species should be confirmed.

*Geranium sanguineum* is a species native to Eurasia, widely used in gardens and naturalized in North America. The specimen collected by *Gandoger s.n.* (MO-1891051) in an imprecise locality of Morocco or Algeria is suspected to be a labeling mistake. Thus, its presence in North Africa should be confirmed. Its presence in Australia, probably as garden-escape, is based on a specimen at AD that could not be studied.

**90. *Geranium swatense*** Schönbr.-Tem. in Rech. f. (ed.), Fl. Iran. 69: 22, tab. 1. 1970. TYPE LOCALITY: "Rechinger 19566, W!... Pakistan:... Swat:... Utror, 2500 m, 23. 8. 1962, Rech. 19566!". TYPE: Pakistan. Khyber Pakhtunkhwa, Swat, Utror, 35°35'N, 72°25'E, 23 Aug 1962, *K.H. Rechinger 19566* (holotype, W!; isotypes, B-100715980!, G-00365994!, M-0243894!).

*Perennial herbs*, 16-60 cm tall. *Root-stock* 7.2-12.1 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* trailing and ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-1.4 mm long and patent, glandular hairs 0.6-2.3 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae (2)2.7-4.5(4.8) cm long, 2.4-6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.72)0.77-0.79(0.86)], polyg-

onal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces and, sometimes, with scattered glandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, (3.5)3.8-9.1(10.3) mm wide at the base [ratio segment width at the base/middle segment length = (0.17)0.21-0.29(0.36)], 6-9-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.21-0.25(0.30)]; petioles up to 14 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1 mm long and patent, glandular hairs 0.4-2.2 mm long; stipules 2.8-5.6 mm long, 0.8-1.7 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin,  $\pm$  glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.5)2.5-4.1(4.7)]; peduncles (42)56-93(109) mm long, with retrorse to uncinat, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.6-2.8 mm long; bracteoles 2.9-5.3 mm long, 0.3-1.1 mm wide, lanceolate, whorled; pedicels (17)21-42(55) mm long, with patent to retrorse, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 1.3-3 mm long. Flowers actinomorphic. *Sepals* (7.2)7.7-9.2(9.8) mm long, 2.3-3.4 mm wide, lanceolate, smooth (with a small dark purple zone at the base), not accrescent, nerves 3, mucro (1)1.4-1.8(2.6) mm long [ratio mucro length/sepal length = 0.11-0.28], with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and patent, glandular hairs 1.2-2.8 mm long on the abaxial surface, glabrous adaxially. *Petals* (14.4)15.1-19(20.8) mm long, (7.7)9.2-12.3(12.8) mm wide, erect-patent, rounded, without claw, purple, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.5-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.9)7-7.9(8.8) mm long, lanceolate, white to pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-1 mm long; anthers 2-2.1 mm long, yellow. Nectaries 5,

hemispheric, glabrous. *Gynoecium* 6-9.4 mm long, pink to purple. *Fruit* (28.8)30-33(34.2) mm long, erect, discharge of seed-ejection type; mericarps 3.3-4.2 mm long, 1.7-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth (usually with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-0.6 mm long and patent, glandular hairs 0.7-1.3 mm long; rostrum 20.3-23.9 mm long, with a narrowed apex 3.3-5.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.6-1.5 mm long; stigmatic remnants 3.8-5.1 mm long, with 5 glabrous lobes. *Seeds* 2.4-3.3 mm long, 1.5-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 250.

*Pollen*. *Geranium*-type (Perveen & Gaiser 1999: 267).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to September.

*Distribution*. This species ranges through northern Pakistan (Fig. 251).

*Habitat*. Meadows and edge of coniferous forests; 2300-4100 m.

*Additional specimens examined*. **Pakistan**. GILGIT-BALTISTAN: Rama, Aston distr., 34°58'N, 75°57'E, 27 July 1946, *Stewart 22897a* (NY, US); Nanga Parbat, NE slopes near Rama, 34°58'N, 75°57'E, 13 Aug. 1955, *Webster 6465* (M); Gilgit, Babusar valley, N of Babusar village, 35°12'N, 74°2'E, 11 Sep. 1983, *Aldén & al. 6119* (GB); near track from Astor to Ramma lake, 35°20'N, 74°50'E, 30 Aug. 1995, *Sinnot 76* (K); Northern Areas, Astor, Nanga Parbat, Mushkin forest, below Mushkin Rest House, 35°29'N, 74°43'E, 5 Sep. 1995, *Dickoré 12718* (M); Northern Areas, Nanga Parbat, Mushkin Rest House, 35°30'N, 74°44'E, 12 Mar. 1996, *Nüsser 243* (B); Northern Areas, Nanga Parbat, Mushkin Rest House, 35°30'N, 74°44'E, 12 Mar. 1996, *Nüsser 254* (B); Northern Areas, Chilas, Diamir, NW above Gor, 35°32'N, 74°29'E, 4 Sep. 1995, *Dickoré 12637* (M); Mushkin forest, Astor valley, 35°42'N, 74°47'E, 27 July 1892, *Duthie 12261* (FI, W); Rama valley, SW of Astor, Gula Aquey, 36°20'N, 75°50'E, 28 July 1967, *Lankester & Pearson 1246* (BM). **Discussion.** *Geranium swatense* is a trailing and ascending small herb with a ± vertical rootstock that bears thin roots. It has opposite leaves, not deeply divided, short and free stipules, long

petals that are glabrous except on the base, glabrous nectaries and narrow staminal filaments. This species is easily distinguished by its long and sometimes entangled glandular hairs on petioles, peduncles, pedicels and sepals.

The affinities of *G. swatense* are difficult to ascertain. At first sight, it resembles *G. collinum* or *G. rosthornii*. *Geranium collinum*, however, has more

Fig. 251. Distribution of *Geranium swatense*.

deeply divided leaves, with more lobes per segment, longer peduncles, shorter petals, hairy nectaries, and staminal filaments with a broad triangular base and an abruptly narrowed apex. *Geranium rosthornii* has broad and connate stipules and an erect habit. Neither of the two has the characteristic glandular hairs of *G. swatense*.

*Geranium swatense* is a rare species from northern Pakistan of which few collections are known. Field study focused on obtaining additional specimens can help elucidate the variability of this species.

**The Papuanum Group**—This group is characterized by its prostrate habit, its opposite, palmatifid or palmatisect leaves and its 1-flowered cymes arranged in monochasial inflorescence. The stems may rooting at nodes and the stipules are ovate, connate or free (although sometimes overlapping). The bracteoles are opposite, usually overlapping its bases one on another giving a sheathed appearance. The petals are of small size, without claw, and usually glabrous. The indumentum is predominantly eglandular.

**91. *Geranium leptodactylon*** Veldkamp, *Blumea* 24(2): 471. 1978. TYPE LOCALITY: "Veldkamp & Stevens 5783

Cotyledons not studied. Fig. 252.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in June.

*Distribution*. This species is endemic to eastern New Guinea (Fig. 253).

*Habitat*. Margins of tussocks of *Styphelia* Sm. and grasses, and on open sandy flats; 3250-3500 m.

*Additional specimens examined*. **Papua New Guinea**. NORTHERN: Goropu Mts., Mt. Suckling, S ridge Goë Dendeniwa, 9°40'S, 148°56'E, 24 June 1972, *Veldkamp & Stevens* 5754 (L). MILNE BAY: Milne bay district, Raba Raba subdistrict, Goe, 9°42'S, 149°2'E, 5 July 1972, *Stevens & Veldkamp*

s.n. (L). Raba Raba subdistrict, Milne bay district, southern end of Goe Dendeniwa, 9°45'S, 148°58'E, 25 June 1972, *Stevens & Veldkamp* s.n. (GH, L).

*Discussion*. *Geranium leptodactylon* is well characterized by its distinctive palmatisect leaves with segments deeply divided into linear lobes. In general aspect *G. leptodactylon* is similar to *G. multipartitum*, an acaulescent species endemic to the Andes. They share deeply divided leaves with linear segments. In both species the pair of basal segments is more or less perpendicular to the plane formed by the remaining segments of the leaf. *Geranium leptodactylon* has a short vertical rootstock with some fusiform roots. Arising from the rosette it has one to several prostrate aerial stems, which root at the nodes. The indument of short eglandular hairs on all parts of the plant is not dense. The stipules are ovate, short, and with an obtuse, rounded apex. This species appears to be restricted to the higher mountains of southeastern New Guinea. According to Veldkamp & Moerman (1978), plants of *G. leptodactylon* are usually sterile. Herbarium material is scarce, and only three sheets have flowers or fruits. Thus, the variation of some descriptive details has not been properly described.

**92. *Geranium clemensiae*** R. Knuth, Repert. Spec. Nov. Regni Veg. 45: 61. 1938. TYPE LOCALITY: "Neu-Guinea: Morobe Distr., Mt. Sarawaket, auf dem Gipfel (Clemens a. 1937 n. 5872 -- Typus in herb. Suckling, Mayu II, 9°40'S, 148°56'E, 14 June 1972, *Veldkamp & Stevens* 5581 (L); Goropu Mts., Mt. Suckling, Mayu II, 9°40'S, 148°56'E, 22 July 1972, *Veldkamp & Stevens* 5991 (HBG, L).

*Discussion.* *Geranium clemensiae* is a variable species and difficult to interpret from the small amount of material available. An additional difficulty is the absence of flowers or rootstocks on most of the sheets. *Geranium clemensiae* shares with *G. leptodactylon* a prostrate aerial stem arising from a short vertical rootstock with some fusiform roots. Both species have palmatisect leaves and an indument of short appressed eglandular hairs. Some leaves of *G. clemensiae* should be considered subpalmatisect since the segments are not completely separated. However, the leaves of *G. leptodactylon* are very distinct because they have more segments, which are dissected into more numerous, very narrow, and deep lobes. The leaves of *G. clemensiae* typically have a middle segment divided into three apical lobes, and in some cases several additional lobelets. In a fragment of *Craven* 2793 (L), it has been verified that the prostrate stem roots at the nodes. This feature should be checked in more individuals of *G. clemensiae* to establish whether it is only occasional or consistent. Each pedicel has two bracteoles that vary from lanceolate to broadly lanceolate. They are not sheathing, but overlap at the base on one side of the pedicel, exposing the opposite part. Ovate stipules are free, but their bases overlap and appear as if they were connate.

Specimens from Mt. Suckling, in the southernmost area of the distribution of *G. clemensiae*, are a bit deviant as Veldkamp & Moerman (1978) indicated. They have longer and nar-

rower stipules, not ovate, and more or less obtuse as in the remaining specimens. Additionally, they have longer peduncles, bracteoles, pedicels, and sepals. In general appearance, however, they are like those from Sarawaket Mountains at the opposite side of the area of distribution for *G. clemensiae*. In both cases they have longer stems, not rooting at the nodes, and larger leaves. Unfortunately, these specimens lack a rootstock.

I have considered *G. clemensiae* to have a similar circumscription to that provided by Veldkamp & Moerman (1978) for *G. subcompositum*. There are, however, two significant differences: (1) I have separated, as a new species, the collections from Star Mountains (*Veldkamp* 6368) (see under *G. castroviejoi*), and (2) I have considered that the plants from Mt. Sarawaket should be included under *G. clemensiae*. The types of *G. clemensiae* and *G. sarawaketense*, both collected on Mt. Sarawaket by Clemens, formerly in B, have been lost. Veldkamp & Moerman (1978) located a duplicate of each at A, indicating that the majority of specimens of these sheets belong to *G. subcompositum*. These authors considered that these duplicate should be rejected as original material because they disagree markedly with the descriptions given by Knuth (1938). I have examined Clemens's collections carefully, however, and I have found only minor discrepancies between the descriptions and the specimens. It should be noted that Knuth's descriptions are not as detailed as could be desired (see also art. 9.19, note 7). Consequently, I have considered that there is no reason to reject *G. clemensiae* and *G. sarawaketense* as "dubious names" and to exclude them in favor of *G. subcompositum* as Veldkamp & Moerman (1978) did. More collections are needed to clarify the circumscription and taxonomy of this species and would help to determine if *G. clemensiae* is simply a variable species or if it should be divided into several taxa.

**93. *Geranium castroviejoi*** Aedo, Syst. Bot. Monogr. 102: 86. 2017. Type locality: "PAPUA NEW GUINEA. Star Mountains, W Sepik, camp 2, Tel Basin, 5°00'S, 141°05'E, 8 Apr 1975, J. F. Veldkamp 6368 (holotype, L; isotype: K!)". TYPE: Papua New Guinea. Star mountains, W Sepik, camp 2, Tel Basin, 5°00'S, 141°05'E, 8 Apr. 1975, J.F. Veldkamp 6368 (holotype, L; isotype, K-001089664!).

*Perennial herbs*, 9-22 cm tall. *Rootstock* 1-3 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, rooting at nodes, stolons present, with short vegetative stems, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite (on buds alternate); leaf laminas (0.7)0.9-1.2(1.3) cm long, 0.8-1.4 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, ± strigose on adaxial surface and with appressed, eglandular hairs restricted to the nerves abaxially; segments 5, in 1 plane, middle segment obtriangular, 0.4-1 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.14], 3(5)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.26-0.40]; petioles up to 6.6 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long; stipules 1.6-2.2 mm long, 0.9-1.7 mm wide, ovate, connate (except on buds), papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.7-0.8]; peduncles 8.9-34.6 mm long, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; bracteoles 1.7-2.3 mm long, 0.8-1.2 mm wide, broadly lanceolate, opposite, overlapping at base to appear sheathing; pedicels 5.6-18.4 mm

long, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. Flowers actinomorphic. *Sepals* 3.1-4.7 mm long, 0.9-1.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-0.8 mm long [ratio mucro length/sepal length = 0.16-0.24], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long and  $\pm$  patent, glandular hairs 0.4-0.9 mm long on the abaxial surface, glabrous adaxial-

ly. *Petals* 5-5.6 mm long, 1.5-1.9 mm wide, erect-patent, rounded, without claw, pink, with scattered hairs on the base of the adaxial surface, ciliate on the basal margin, with hairs ca. 0.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.6-2.5 mm long, lanceolate with an abruptly narrowed apex, unknown color, with scattered hairs ca. 0.1 mm long on the abaxial surface and margin;

anthers 0.5-0.6 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.4-2.6 mm long, unknown color. *Fruit* 11.4-12.8 mm long, erect, discharge of seed-ejection type; mericarps 2.2-3 mm long, 1-1.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.3 mm long; rostrum 7.8-9 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 1-1.2 mm long, with 5 glabrous lobes. *Seeds* 1.9-2 mm long, 0.9-1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 256.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in April.

*Distribution*. This species is endemic to central New Guinea (Fig. 257).

*Habitat*. Bank of rivulets among tall grasses, and edge of conifer forests; 2900-3100 m.

*Additional specimens examined*. **Papua New Guinea**. WEST SEPIK: Star Mts., Telefomin subdistrict, W Sepik, ca. 2 km SE of Mt. Capella summit ridge, 4°58'S, 141°6'E, 10 Apr. 1975, Barker & Umba s.n. (L).

*Discussion*. Veldkamp & Moerman (1978) examined the collection Veldkamp 6368 and noted the great dis-

Fig. 256. *Geranium castroviejoi*. a. Habit. b. Leaf, adaxial surface. c. Detail of leaf indument. d. Leaf, abaxial surface. e. Stipules of prostrate stems. f. Bracteoles. g. tance (over 700 km) between the locality of their *G. subcompositum* (here *G. clemensiae*) and the specimens collected from the Star Mountains. They overlooked, however, some important morphological differences that permit recognition of the plants from the Star Mountains as a distinct species. The most relevant difference is presence of patent glandular hairs on the sepals, especially towards the base, in *G. castroviejoi*. The leaves of *G. castroviejoi* and *G. clemensiae* are quite similar in shape, but not in the indument of the abaxial surface: leaves of the former have distinctive lines of appressed eglandular hairs on the nerves, while the surface between the nerves has a more or less dense indument in *G. clemensiae*, so the nerves do not stand out as in *G. castroviejoi*. The staminal filaments of *G. castroviejoi* are abruptly narrowed at the apex. In some flowers there are a pair of auricles (one on each side) just at the point where the filament narrows. However, the scarce available material does not permit us to establish whether it is a consistent feature of the species or not. For the same reason, the underground parts of *G. castroviejoi* are not well known. It is interesting to note that the leaves are alternate toward the apex and have free stipules whereas those of the middle of shoot are opposite and have connate stipules.

**94. *Geranium monticola*** Ridl., Trans. Linn. Soc. London, Bot. 9(1): 23. 1916. TYPE LOCALITY: "Camp XIII, 10,500 ft.". TYPE: Indonesia. Papua, Mt. Carstensz, Camp XIII, 4°06'S, 137°10'E, 1912, C.B. Kloss s.n. (lectotype, designated by Veldkamp & Moerman 1978: 472, BM-000075364!).

*Perennial herbs*, 3-30 cm tall. *Rootstock* 2.4-6.2 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, not rooting at nodes, stolons absent, with short veg-

etative stems, with retrorse, usually appressed, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite (on buds alternate); leaf laminae (0.5)0.7-1.1(1.5) cm long, 0.5-1.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.68-0.80(0.88)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with scattered long hairs or strigose on adaxial surface and sericeous, with antrorse, appressed, eglandular hairs abaxially; segments 5(7), in 1 plane, middle segment obtriangular, 0.9-2 mm wide at the base [ratio segment width at the base/middle segment length = 0.22-0.33], (1)3(4)-lobed at apex [ratio secondary sinus length/middle segment length = 0.13-0.31]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.6 mm long; stipules 2.1-4.9 mm long, 1.5-3.3 mm wide, ovate, connate (except on buds), papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.4-0.9(1.1)]; peduncles 3.5-21.7 mm long, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long; bracteoles 1.9-4.9 mm long, 1.2-2.7 mm wide, broadly lanceolate, opposite, overlapping at base to appear sheathing; pedicels 2.9-28.3 mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long. Flowers actinomorphic. *Sepals* (3)3.5-4.7(5.7) mm long, 1.1-2.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.8 mm long [ratio mucro length/sepal length = 0.12-0.20], sericeous, with antrorse, appressed, eglandular hairs 0.2-0.4 mm long and scattered, patent, eglandular and glandular hairs 0.7-1.4 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.7)5.2-6.5(7.1) mm long, 1.7-3.1 mm wide, erect-patent, rounded, without claw, purple, rarely white, glabrous. *Stamens* 10, both

whorls bearing anthers; filaments 1.8-2.3 mm long, lanceolate with an abruptly narrowed apex, yellow, glabrous on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers 0.4-0.7 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.1-3.3 mm long, yellow. *Fruit* 7.9-12.5 mm long, erect, discharge of seed-ejection type; mericarps 1.6-2.8 mm long, 1-1.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosus, without a basal prong, brown, sericeous, with antrorse, ± appressed, eglandular hairs 0.1-0.4 mm long; rostrum 3.7-8.1 mm long, without a narrowed apex, not twisted, sericeous, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.7-1.2 mm long, with 5 hairy lobes. *Seeds* 1.4-1.8 mm long, 0.7-1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 258.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to November.

*Distribution*. This species ranges through central New Guinea (Fig. 259).

*Habitat*. Sandy banks of streams in subalpine grassland, and open rocky soil with outcrops of limestone; 3100-4700 m.

*Representative specimens examined*.

**Discussion.** *Geranium monticola* is usually a cushion-like herb, with more or less elongated prostrate stems not rooting at the nodes. The rootstock is vertical and with thin roots. In well-developed plants the prostrate stems are more or less branched. Buds covered by stipules and petiole remnants are produced toward the apex of the branches of the rootstock and on the nodes of the prostrate stems. It should be noted that the leaves of the buds are alternate and with free stipules whereas those of the prostrate stems are opposite with connate stipules such as are present in *G. castroviejoi*. The bracteoles of *G. monticola* are strictly opposite and imbricate (Carolin 1964: 446), but not sheathing. Another important feature of *G. monticola* is the calyx indument. The abaxial surface of the sepals is densely covered by short (0.2-0.4 mm), appressed eglandular hairs. In addition, on the basal half there are more or less abundant long (0.7-1.4 mm) spreading hairs. These hairs are both glandular and eglandular, but the proportions of the two types vary. Furthermore, glandular hairs have an apical cell slightly wider than the peduncle, but this cell is sometimes lost in dried specimens and the hairs then appear eglandular. The most distinctive feature of *G. monticola*, however, is the sericeous indument of the abaxial surface of the leaves. Veldkamp & Moerman (1978: 472) pointed out that the indument of the adaxial surface of the leaves of *G. monticola* is

variable. In the area of Mt. Carstensz some plants have the adaxial surface of the leaves glabrous, while others have scattered, erect-patent, long hairs, and finally some have a dense, strigose indument of appressed hairs. On some herbarium sheets mixed collections can be found [*Wissel & Colijn* 103 (L), *Sands* 7085 (K), *Kloss s.n.* (BM)], which suggests that this feature does not have taxonomic importance. Eastern populations, except one from Mt. Wilhelmina, which is glabrous, have the abaxial surface of the leaves strigose (*Brass & Meijer Drees* 10185, A, L). The shape of the middle leaf segment is also variable because of the variation in lobing: plants with three-lobed segments may be mixed with those with entire middle segments in the same gathering. Two localities (Mt. Karoma and Mt. Bangeta) are far from the main area of distribution for *G. monticola*. Unfortunately, the collections from those areas are insufficient to ascertain if they can be differentiated. The specimens from Mt. Karoma (*Veldkamp & Wiakabu* 7713, L) form compact cushions with smaller leaves. The middle leaf segment is usually entire, although there are some leaves with 3-lobed middle segments. It is also interesting to note that their leaves have 7 segments, not 5, as in the remaining collections of *G. monticola*. The cymules have a very short peduncle and apparently no pedicel. These features should be checked in more specimens to establish if they are occasional or not. The specimen from Mt. Bangeta (*Royen* 20046, L) is quite similar to other collections of *G. monticola* except for its short cymules, which also lack pedicels. Plants from both localities should be carefully re-collected to fill in the gaps in the descriptions and to clarify their status.

TYPE: Indonesia. Papua, Wilhelmina, lake Habbema, 4°15'S, 138°53'E, Aug. 1938, *L.J. Brass* 9207 (holotype, L-0018357!; isotypes, A-00043676!, BO, BRI-AQ0221062 image!, LAE).

*Geranium lacustre* Veldkamp, *Blumea* 24(2): 471. 1978. TYPE LOCALITY: "Versteeg 2494 (L; iso in BO, n.v.), Nova Guinea (Mt. Wilhelmina)". TYPE: Indonesia. Papua. Mt. Wilhelmina, near the lake, 4°15'S, 138°53'E, 17 Feb. 1913, *G.M. Versteeg* 2494 (holotype, L-0018346!; isotype, BO).

*Perennial herbs*, 3-41 cm tall. *Rootstock* 1.6-3.5 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, rooting at nodes, stolons present, with short vegetative stems, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite (on buds alternate); leaf laminae (0.5)0.6-0.8(1.1) cm long, 0.6-1.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.63-0.83], polygonal in outline, base cordate, not coriaceous, with nerves not projected, glabrous or strigose on adaxial surface, and with appressed, eglandular hairs restricted to the nerves on the abaxial surface; segments 5, in 1 plane, middle segment obtriangular or broadly lanceolate, 0.7-1.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.33], 1-3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.26-0.40]; petioles up to 5.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; stipules 1.3-2.2 mm long, 0.8-1.5 mm wide, ovate, free (sometimes connate at the apex of stem), papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.4-0.9]; peduncles 1.8-8.8 mm long, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long; bracteoles 1.8-3 mm long, 0.8-1.6 mm wide, broadly

lanceolate, opposite, overlapping at base to appear sheathing; pedicels 2.2-10.7 mm long, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. Flowers actinomorphic. *Sepals* (2.7)3-4.3(4.6) mm long, 1.3-1.9 mm wide, lanceolate to broadly lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.8 mm long [ratio mucro length/sepal length = 0.13-0.25],

with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long and  $\pm$  patent, glandular hairs 0.4-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.1)4.6-5.4 mm long, 1.4-2.1 mm wide, erect-patent, rounded, without claw, pink, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 1.7-2.3 mm long, lanceolate with an abruptly narrowed apex, yel-

low, with scattered hairs ca. 0.1 mm long on the margin; anthers 0.4-0.6 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.6-2.7 mm long, unknown color. *Fruit* 8.2-11.6 mm long, erect, discharge of seed-ejection type; mericarps 1.8-2.6 mm long, 0.7-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long; rostrum 5.5-8.1 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.7-1.2 mm long, with 5 hairy lobes. *Seeds* 1.5-1.7 mm long, 0.9-1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 260.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to September.

*Distribution*. This species is endemic to central New Guinea (Fig. 261).

*Habitat*. Open boggy grounds, grassland, banks of streams and treefern savannas; 2300-4000 m.

*Additional specimens examined*. **Indonesia**. PAPUA: 2 km E of Wilhelmina top, 4°15'S, 138°53'E, Sep. 1938, *Brass & Meijer Drees 10186* (L); 11 km NE of Wilhelmina top, 4°15'S, 138°53'E, Sep. 1938, *Brass & Meijer Drees 9813* (A, L); Mt. Trikora, base of False Peak, to the N, 4°15'S, 138°45'E,

**Discussion.** *Geranium wilhelminae* is a small herb with a weak, vertical rootstock, slender roots, and some prostrate, aerial stems rooting at the nodes. It should be noted that the leaves of prostrate stems are opposite nearer to the base of the rosette but become alternate toward the stem apex. The stipules are ovate and usually free, but at the apical nodes of the prostrate stems there are occasional, partially connate stipules. The bracteoles of *G. wilhelminae* are broad and strictly opposite and imbricate, but not sheathing. The calyx indument comprises both short appressed eglandular hairs, usually along the nerves and long, spreading glandular hairs on the basal half of the sepals. The leaves of *G. wilhelminae* are palmatifid, with five segments. The appressed eglandular hairs are mostly restricted to the nerves on the abaxial surface. The indument of the adaxial surface and shape of the leaf segments are variable. Collections from Mt. Wilhelmina are predominantly glabrous on the adaxial surface with unlobed, broadly lanceolate segments. Even in the same gathering from this area, however, there are specimens with 2- or 3-lobed obtriangular segments and/or with a hairy adaxial surface. The density of the indument varies from a few scattered hairs to more or less patchily strigose. The only collection

from the Valentijn Mountains is sterile, but the leaves are quite similar to those on plants from Mt. Wilhelmina. Plants collected from Mt. Trikora are more variable: the leaves frequently have three-lobed segments, but again within the same gathering there are usually unlobed segments as well. *Geranium lacustre* was described from the same locality as *G. wilhelminae*, although it was compared with *G. papuanum* instead of with *G. wilhelminae*. The two fragments of the type of *G. lacustre* have some leaves with unlobed segments and others with two or three lobes. The density of the hairs on the adaxial surface is also variable. Both specimens fall easily within the range of variability of *G. wilhelminae*. *Geranium wilhelminae* bears some resemblance to *G. castroviejoi* because of the glandular hairs on the sepals and hairs on the nerves of the abaxial surface of the leaves. The latter, however, has palmatisect leaves with narrow segments (never unlobed) and longer peduncles and pedicels. The two species occupy allopatric distributions.

---

**96. *Geranium hyperacrimon*** Veldkamp, *Blumea* 24(2): 470. 1978. TYPE LOCALITY: "NGF 16010 v. Royen (L; iso in LAE), Nova Guinea (Mt. Wilhelm)". TYPE: Papua New Guinea. Monolithic Rock to summit Mt. Wilhelm, 5°45'S, 145°05'E, 26 Sep. 1962, *P. van Royen NGF 16010* (holotype, L-0018345; isotype, LAE).

*Perennial herbs*, 4-12 cm tall. *Rootstock* 1-2.1 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, rooting at nodes, stolons present, with short vegetative stems, with ± patent, eglandular hairs 0.1-0.2 mm long and, very rare, patent, glandular hairs 0.2-0.3 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite (on buds alternate); leaf laminae (0.3)0.5-0.8(1) cm long, 0.5-1.1 cm wide, not pel-

tate, palmatifid [ratio main-sinus length/middle segment length = 0.52-0.63(0.68)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, glabrous on the adaxial surface, and with scattered, antrorse, appressed, eglandular hairs, on the abaxial surface and margin; segments (5)7, in 1 plane, middle segment broadly lanceolate, 0.8-2.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.30-0.45], entire; petioles up to 3.7 cm long, without abscission zone, terete, not swollen, not deflexed in age, with ± patent, eglandular hairs 0.1-0.2 mm long and, exceptionally, patent, glandular hairs 0.2-0.3 mm long; stipules 0.8-1.9 mm long, 0.7-1.3 mm wide, ovate, free (although sometimes overlapping), papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.6-1.6]; peduncles 1.7-5.1 mm long, with ± patent, eglandular hairs 0.1-0.2 mm long; bracteoles 1-1.9 mm long, 0.8-1.3 mm wide, broadly lanceolate, opposite, overlapping at base to appear sheathing; pedicels 2.6-8 mm long, with ± patent, eglandular hairs 0.1-0.2 mm long. Flowers actinomorphic. *Sepals* (3.1)3.3-4.2(4.6) mm long, 1.4-2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.4 mm long [ratio mucro length/sepal length = 0.05-0.10], with antrorse, ± appressed, eglandular hairs 0.2-0.4 mm long on the abaxial surface, glabrous adaxially. *Petals* 4.8-6.8 mm long, 1.9-3 mm wide, erect-patent, rounded, without claw, pink, glabrous or sparsely ciliate on the basal margin, with hairs ca. 0.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.4-2.9 mm long, lanceolate with an abruptly narrowed apex, unknown color, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers 0.4-0.5 mm long, unknown color. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 2.9-4.1 mm long,

unknown color. *Fruit* 10.4-11.4 mm long, erect, discharge of seed-ejection type; mericarps 1.6-2 mm long, 0.9-1.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.2 mm long; rostrum 6.8-7.4 mm long, without a narrowed

apex, not twisted, with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 0.7-1.2 mm long, with 5 glabrous lobes. *Seeds* 1.3-1.5 mm long, 0.9-1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 262.

*Pollen*. Ornamentation not studied. *Chromosome number*.  $2n = 56$ .

*Phenology*. Collected in flower from June to September.

*Distribution*. This species is endemic to central New Guinea (Fig. 263).

*Habitat*. Open patches of poor, well-drained soil, among low grasses and other herbs; 3650-4350 m.

*Additional specimens examined. Papua New Guinea*. EASTERN HIGHLANDS: Mt. Wilhelm, W Pinde valley, 5°45'S, 145°5'E, 1965, *Balgooy* 187 (L); Mt. Wilhelm, Brass Tarn, small ridge E of Lake, 5°45'S, 145°5'E, 6 May 1965, *Balgooy* 235 (A, L, NSW); Mt. Wilhelm, 5°45'S, 145°5'E, 13 June 1960, *Borgmann* 92 (L). SOUTHERN HIGHLANDS: western summit of Mt. Giluwe, 6°5'S, 143°50'E, 21 Aug. 1961, *Schodde* 1946 (K, L).

*Discussion*. *Geranium hyperacron* is similar to *G. wilhelminae* in general appearance. Both are small herbs with a weak, vertical rootstock with slim roots and some prostrate stems rooting at the nodes. They also share opposite leaves on prostrate stems and alternate ones on the buds. A more careful examination, however, reveals several differences. The stems and petioles of *G. hyperacron* have short and spreading eglandular hairs and scattered glandular hairs (especially toward the bases of the petioles). In contrast, the indument on the stems and petioles of *G. wilhelminae* consists of only short, appressed eglandular hairs. The leaves of *G. hyperacron* are consistently glabrous on the adaxial surface and almost always have seven broadly lan-

length = 0.11-0.22], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long on the abaxial surface, glabrous adaxially. *Petals* 4.6-5.3 mm long, 1.4-2.5 mm wide, erect-patent, rounded, without claw, white, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 1.8-2 mm long, lanceolate with an abruptly narrowed apex, unknown color, glabrous or with scattered hairs 0.1-0.2 mm long on the abaxial surface and margin; anthers 0.4-0.5 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.9-2.2 mm long, unknown color. *Fruit* 9.2-9.9 mm long, erect, discharge of seed-ejection type; mericarps 1.8-1.9 mm long, 1-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.2 mm long; rostrum 5.1-5.8 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 0.4-0.8 mm long, with 5 glabrous lobes. *Seeds* 1.3-1.4 mm long, 0.9-1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 264.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in January.

*Distribution*. This species is endemic to eastern New Guinea (Fig. 265).

*Habitat*. Fire-induced alpine meadows; ca. 3050 m.

*Discussion*. *Geranium editum* is a rare species known only from the type specimen. The scarce available material is probably insufficient to ascertain its variability. Although similar to *G. hyperacrium* in general appearance and leaf shape, *G. editum* has only eglandular hairs on the stems and petioles. Leaves of *G. editum* have scattered eglandular hairs on the adaxial surface, sometimes in patches, while the leaves are glabrous adaxially in *G. hyperacrium*. In addition, the peduncles of *G. editum* are significantly longer than in *G. hyperacrium*.

Fig. 267. Distribution of *Geranium papuanum*.

from New Guinea because of its long petals. It is also easy to identify by its fruits, which have a rostrum with a significantly narrowed apex. The general aspect of *G. papuanum* is similar to that of other species from New Guinea, with prostrate stems rooting at the nodes. As noted also in *G. monticola*, the stems can be branched. The underground parts of *G. papuanum* are not well known, however, because most herbarium specimens are fragments. The rootstock appears to be vertical and the roots slender, although this needs to be confirmed with more comprehensive collections. The leaves have five segments, which are 3-lobed at the apex. The indument of the adaxial surface of the leaves shows some variation. The surface can be almost glabrous or have scattered long hairs (0.5-1 mm long), which may sometimes occur in patches. Veldkamp & Moerman (1978: 474) tentatively included within *G. papuanum* a specimen collected from the Star Mountains having short sepals with glandular hairs and palmatisect leaves (Barker & Umba s.n., L-380874). I included that collection in the new species, *G. castroviejoi* (Aedo 2017a).

**99. *Geranium whartonianum*** Veldkamp, Blumea 24(2): 476. 1978. TYPE LOCALITY: "LAE 61390 Croft et al. (L; iso in LAE; BRI, n.v.), Nova Guinea (Mt. Albert Edward)". TYPE: Papua New Guinea. Mt. Albert Edward, 8°25'S, 147°20'E, 21 June 1974, J.R. Croft & al. s.n. (holotype, LAE-61390; isotypes, BRI-AQ0353164 image!, L-0018358!).

*Perennial herbs*, 10-34 cm tall. *Rootstock* 1.6-5.1 mm in diameter, vertical, not tuberculate, not turnip-shaped, with  $\pm$  thickened roots. *Stem* prostrate, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae (0.6)1-1.3(1.8) cm long, 1-2.9 cm wide, not

peltate, palmatifid [ratio main-sinus length/middle segment length = 0.62-0.70(0.76)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, glabrous or with scattered long hairs on adaxial surface,  $\pm$  strigose abaxially; segments 5, in 1 plane, middle segment obtriangular, 1.7-3.6 mm wide at the base [ratio segment width at the base/

middle segment length = 0.24-0.40], 3-lobed in distal half [ratio secondary sinus length/middle segment length = (0.09)0.12-0.17(0.25)]; petioles up to 23 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; stipules 1.4-2.6 mm long, 0.6-1.2 mm wide, ovate, free, papery, brownish red,

(A); Central district, Wharton Range, Murray Pass, 8°32'S, 147°21'E, June 1933, Brass 4637 (A, NY); Central district, Goilala subdistrict, Murray Pass, Mt. Albert Edward region, above Sidibamu, 8°32'S, 147°21'E, 7 Aug. 1968, Woods 3004 (E, GH, L).

*Discussion*. *Geranium whartonianum* is a small herb, with more or less elongated, prostrate stems not rooting at the nodes. The rootstock is vertical and with  $\pm$  fusiform roots. *Geranium whartonianum* has leaves with five segments, which are 3-lobed at the apex. The stipules are ovate and free. As in *G. papuanum*, the indument of the leaf adaxial surface can vary from glabrous to having scattered, spreading hairs 0.6-0.9 mm long, which may sometimes occur in patches. The range of variation can be found within the same gathering. This species

also has many similarities with *G. niginiense*: for further discussion, see under that species.

**100. *Geranium balgooyi*** Veldkamp, Blumea 24(2): 469. 1978. TYPE LOCALITY: "v. Balgooy 924 (L; iso in LAE), Nova Guinea (Mt. Wilhelm)". TYPE: Papua New Guinea. Mt. Wilhelm, 5°45'S, 145°5'E, 29 June 1965, M.M. Balgooy 924 (holotype, L-0018338!; isotypes, C-10018763!, K-000729533!, LAE).

*Perennial herbs*, 3-25 cm tall. *Rootstock* 2.1-4.7 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas (0.7)1-1.4(1.8) cm long, 0.8-1.1(2) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.64-0.75], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 1.8-2(3.6) mm wide at the base [ratio segment width at the base/middle segment length = 0.24-0.38], 3-5(7)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.17-0.31]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long; stipules 2-3.7 mm long, 1.1-2.4 mm wide, ovate, free (although overlapping), papery, brownish red, glabrous or with scattered, eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.5-1]; peduncles 1.5-5(9) mm long, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; bracteoles 2.1-5.1 mm long,

0.9-2.1 mm wide, broadly lanceolate, subopposite, overlapping at base on one side of the pedicel, exposing the opposite part; pedicels absent or (2.4)4.1-25.4(41.8) mm long, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. Flowers actinomorphic. *Sepals* (2.6)3.3-4.6(5.5) mm long, 1.3-2.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.8 mm long [ratio mucro length/se-

pal length = 0.09-0.22], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long and  $\pm$  patent, eglandular hairs 0.4-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.2)5-5.4(5.6) mm long, 1.8-3.2 mm wide, erect-patent, rounded, without claw, white to pink, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 1.3-2.2 mm long, lanceolate with an abruptly narrowed apex,

unknown color, glabrous; anthers 0.3-0.4 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.7-2.9 mm long, unknown color. *Fruit* 8.9-10.4 mm long, erect, discharge of seed-ejection type; mericarps 2-2.8 mm long, 0.8-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callos, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.3 mm long; rostrum 5.2-6.5 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.6-1.3 mm long, with 5 glabrous lobes. *Seeds* 1.7-1.9 mm long, 1-1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 270.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to July.

*Distribution*. This species is endemic to central and eastern New Guinea (Fig. 271).

*Habitat*. Wet peaty soil among grass tussocks together mosses and *Pilea* Lindl. or epiphytic on *Cyathea* Sm.; 3100-4000 m.

**Discussion.** *Geranium balgooyi* is a small herb with more or less elongate, prostrate stems not rooting at the nodes. The rootstock is vertical and bears  $\pm$  fusiform roots. *Geranium balgooyi* has leaves with five segments. The leaf segments are mostly 3-lobed at the apex but in the same gathering some 5-lobed segments (very rarely 7-lobed) are usually to be found. The stipules are broadly ovate and free. The leaf indument consists of short, appressed eglandular hairs uniformly covering both surfaces. However, the most distinctive feature of this species is its short or absent pedicels, which are usually 1.5-5 mm long, and only rarely reaching even 9 mm in length. Within the same gathering are others with shorter or absent pedicels. The bracteoles are significantly longer, although they are indistinguishable from stipules in cymules lacking a pedicel. The sepals of *G. balgooyi* is covered with short, appressed eglandular hairs mainly toward the abaxial base and margins. On the margins are some spreading, eglandular hairs are found, which are appreciably longer than those found in other species, such as *G. whartonianum*. One collection of *G. balgooyi* has been made from from Star Mountains about 400 km west of the main area of distribution of the species. The specimen has sepals with marginal hairs a bit longer than those from Mt. Wilhelm, but otherwise it falls into the established variability of the species. *Geranium balgooyi* is sympatric with *G. hyperacri-*on, which also has short pedicels. The latter, however, is easily distinguished by its prostrate stems rooting at the nodes, leaves with seven segments, broadly lanceolate and unlobed at the apex, glabrous on the adaxial surface, and by its connate stipules.

**101. *Geranium niuginiense*** Veldkamp, *Blumea* 24(2): 473. 1978. TYPE LOCALITY: "v. Balgooy 296 (L; iso in LAE), Nova Guinea (Mt. Wilhelm)". TYPE: Papua New Guinea. Mt. Wilhelm, S of lake Pinde, 5°45'S, 145°5'E, 11 May 1965, *M.M. Balgooy* 296 (holotype, L-0018350!; isotype, LAE).

*Perennial herbs*, 5-85 cm tall. *Root-stock* 1.8-3 mm in diameter, vertical, not tuberculate, not turnip-shaped, with  $\pm$  thickened roots. *Stem* prostrate, leafy, sometimes rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, appressed, eglandular hairs 0.1-0.4 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas (0.7)1.2-1.6(2.9) cm long, 0.9-2.1(4) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.66)0.74-0.81(0.84)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, strigose on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 0.9-2.4(4.7) mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.34], 3-lobed in distal half [ratio secondary sinus length/middle segment length = (0.10)0.18-0.26(0.30)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, appressed, eglandular hairs 0.1-0.5 mm long; stipules (1.2)1.8-2.9(3.5) mm long, 0.5-1.3(1.7) mm wide, ovate, rarely lanceolate, usually free, rarely  $\pm$  connate, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.5)0.7-3.1]; peduncles (7.2)16.5-33.6(55.7) mm long, with patent to retrorse, appressed, eglandular hairs 0.1-0.6 mm long; bracteoles (1.4)2-3(3.3) mm long, (0.5)0.7-1(1.5) mm wide, lanceolate to broadly lanceolate, opposite, usually overlapping at base to appear sheathing; pedicels (4.2)10-23(40.8) mm long,

with patent to retrorse, appressed, eglandular hairs 0.1-0.7 mm long. Flowers actinomorphic. *Sepals* (3.5)4.1-4.9(5.3) mm long, 1.1-2.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.3)0.5-0.7(0.8) mm long [ratio mucro length/sepal length = 0.09-0.22], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 4.2-6.3(7.1) mm long, 1.4-4.3 mm wide, erect-patent, rounded, without claw, white or pale pink, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 1.7-3.2 mm long, lanceolate, unknown color, glabrous or with scattered hairs 0.1-0.2 mm long on the abaxial surface and margin; anthers 0.4-0.6 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.1-3.6 mm long, unknown color. *Fruit* (9.9)11.6-16.1 mm long, erect, discharge of seed-ejection type; mericarps 2-2.8 mm long, 0.9-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-0.4 mm long; rostrum 6.3-11.3 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 0.6-1.5 mm long, with 5 hairy lobes. *Seeds* 1.6-2.3 mm long, 1.1-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 272.

*Pollen.* Ornamentation not studied.

*Discussion.* *Geranium niuginiense* is a small herb with more or less elongated, prostrate stems sometimes rooting at the nodes. The rootstock is vertical with  $\pm$  fusiform roots. *Geranium niuginiense* has leaves with five segments that are 3-lobed at the apices. The leaf indument consists of short, appressed eglandular hairs uniformly covering both surfaces. Veldkamp & Moerman (1978: 473) indicated that *G. niuginiense* is a variable species and that specimens from the Owen Stanley Range (the southeastern subarea, between 7° and 9° S) have more deeply divided

Fig. 273. Distribution of *Geranium niuginiense*.

leaves and larger flowers than those from Mt. Wilhelm (the northwestern subarea, south to 7° S). I compared specimens from the two subareas and found them to be similar in petal length, sepal length, and main-sinus length/middle segment length ratio. However, I noted some differences in indument and shape of the stipules and bracteoles. Specimens from the Owen Stanley Range display patent indument on the stems, petioles, and pedicels while plants from the northwestern subarea usually have retrorsely appressed hairs. The stipules and bracteoles from the first subarea are constantly lanceolate, while in the second subarea the stipules are predominantly ovate and the bracteoles are mainly broadly lanceolate. Different combinations of these features advise against a taxonomic recognition of these variants. *Geranium whartonianum* is quite similar to *G. niuginiense* and occupies a geographic distribution between the two subareas where *G. niuginiense* occurs. The most striking difference between the two is the indument of the adaxial surface of the leaves. The leaves of *G. whartonianum* are glabrous or with scattered long hairs mainly near the margins of the adaxial surface while the leaves of *G. niuginiense* are uniformly covered by short hairs. In addition, the leaves of *G. niuginiense* are usually more deeply divided both in the main sinus and in the secondary sinus, the bracteoles and sepal mucro are usually longer, and the staminal filaments are usually shorter, but there is some overlap in all of these characters. *Geranium balgooyi* is partially sympatric with *G. niuginiense* in the surroundings of Mt. Wilhelm. It can be distinguished from *G. niuginiense* by its shorter pedicels and fruits, longer bracteoles, and staminal filaments with an abruptly narrowed apex. *Geranium niuginiense* is quite similar to *G. potentilloides*, an endemic from Australia and New Zealand. Carolin (1965: 339) placed *G. niuginiense* in synonymy under *G. potentilloides*. However several differ-

ences between the two species may be underscored. The leaves of *G. niuginiense* have the middle segment 3-lobed at the apex while the middle segment of *G. potentilloides* is variable and often has more than three lobes (up to nine). In addition, leaves of *G. niuginiense* are always small, (0.7)1.2-1.6(2.9) cm long, while in *G. potentilloides* the leaves show some size variation, (0.8)1.2-3.3(3.8) cm long, which overlaps with that of *G. niuginiense*. *Geranium niuginiense* has bracteoles relatively wider and fruits without a narrowed rostrum apex. All these traits show some degree of overlap, which increases the difficulty of preparing keys to the species. The concurrence of all these minor differences together with the geographical isolation, however, suggests that *G. niuginiense* should be separated as an independent species, as Veldkamp & Moerman (1978: 473) proposed. *Geranium niuginiense* is also difficult to separate from *G. frigidurbis*, an endemic from Sulawesi. For more details see the discussion under *G. frigidurbis*.

---

**The Solanderi Group**—This group is characterized by its erect to ascending habit, its turnip-shaped rootstock, its opposite, usually palmatifid leaves and its usually 2-flowered cymes arranged in monochasial inflorescence. The stipules are lanceolate and free. The bracteoles are whorled, not overlapping. The petals are of medium size, usually without claw and glabrous, except on the base.

**Discussion.** *Geranium solanderi* is characterized by a turnip-shaped rootstock, 2-flowered cymules with patent eglandular hairs on the peduncles and pedicels, short petals only 3-8.5 mm long, and fruits with a short narrowed apex or lacking a narrowed apex, and relatively short persistent stigma lobes. Gardner (1984) studied the variability of *G. solanderi* in New Zealand and distinguished two variants from the common form, one called "large petals" and the other called "coarse hairs". The name *G. gardneri* was proposed by de Lange & al. (2005a) to recognize the "coarse hairs" form, and these authors identified additional morphological features to differentiate *G. gardneri* from *G. solanderi*: a more cylindrical tap-root [here rootstock], less divided leaves, and seeds with shorter alveolae. I confirmed in this study, however, that intermediate character states or a combination of the features diagnostic of each form are

common in Australian material. All of these features, as well as petal length and coarseness and direction of the hairs, vary in a continuum and independently, which makes more difficult the recognition of discrete taxa. De Lange & al. (2005a: 566) quoted Smith (1999), who claimed that Australian intermediate forms between *G. gardneri* and *G. solanderi* should be recognized at the species rank. De Lange (2005a: 566) indicated that *G. gardneri* ". . . showed no close affinity, with *G. solanderi* sens. str. being nested within a clade involving *G. retrorsum* L'Hér. ex DC., and *G. gardneri* with *G. potentilloides*, a result which has independent support . . ." on the basis of an unpublished study of DNA sequences. However, Mitchell & al. (2009: 26) analyzed DNA sequences of New Zealand species of *Geranium* and found that *G. gardneri* is included in a clade (with 100% posterior probability) together with *G. retrorsum*, "*G. aff. retrorsum*", and *G. solanderi*. This clade had three separate branches: (1) *G. solanderi* alone, (2) two samples of "*G. aff. retrorsum*", grouped with 95 % posterior probability, and (3) a subclade (without posterior probability shown) comprising the two samples of *G. retrorsum* (grouped with 100% posterior probability) and the two samples identified as *G. gardneri* (grouped with 100% posterior probability). The clade was thus unresolved at the species level (at least not with a sufficient probability) and included only one sample of *G. solanderi* and no plants from Australia.

Another remarkable form was that described by Carolin (1965: 353) as *G. drummondii* from SW Australia. It is characterized by a dense, entangled indument especially on the pedicels, sepals, and mericarps. However intermediate forms are common in this area and in other Australian localities.

*Geranium solanderi* has predominantly 2-flowered cymules, but herbarium specimens with some 1-flowered cymules, especially toward the apex of inflorescence, are frequent. Three specimens of *G. so-*

*landeri* [*Hosking 2167* (CANB), *Jackson 87* (L, US), *Moore 8733* (CANB)] have widely spreading glandular hairs on stem and inflorescence, which seems to be an exceptional feature in this species. *Geranium solanderi* strongly resembles *G. berterioanum*, which is an endemic from the Andes. In *G. berterioanum* glandular forms are frequent, and the bracteoles (2.5-6.7 mm), sepals [(4.4)5.4-6.1(7)] mm, and persistent stigma lobes [(1.1)1.3-1.7(2.1) mm] are all longer than in *G. solanderi*. In summary, *G. solanderi* appears to be a very variable species with some remarkable forms not yet fully resolved. Thus, any attempt to split it might be premature and unfeasible. *Geranium retrorsum* and *G. solanderi* are similar species, many times difficult to differentiate, especially on herbarium specimens. It is particularly problematic in the case of forms of *G. solanderi* with "coarse hairs" where the indument of the pedicel and peduncle consists of more or less retrorse but not appressed, hairs. However, in favor of the independence of both species, Carolin (1965: 349) stated that "It [*G. retrorsum*] grows in association with this latter species [*G. solanderi*] but does not appear to hybridize". Except for the short sepals, with a proportionally long mucro and scattered hairs, fragments of *G. homeanum*, collected without rootstock, are also difficult to separate with certainty from *G. solanderi*. According to Carolin (1965), the seed coat of *G. homeanum* is a bit different from the seed coat of *G. retrorsum* and *G. solanderi*. In *G. homeanum* the dorsal alveolae are shallow and mostly elongate, while in *G. retrorsum* and especially in *G. solanderi* they are isolateral and deeper.

pressed, eglandular hairs 0.1-0.6 mm long. Flowers actinomorphic. *Sepals* (3.7)4.1-5.8(6.3) mm long, 2.2-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.1-0.2(0.3) mm long [ratio mucro length/sepal length = 0.02-0.07], with erect-patent, eglandular hairs 0.2-0.8 mm long on the abaxial surface,  $\pm$  glabrous adaxially. *Petals* (4)4.2-6.2 mm long, 2.3-4.4 mm wide, erect-patent, rounded, without claw, pink with white base, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.4-3.1 mm long, lanceolate, unknown color, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.3 mm long; anthers 0.5-0.6 mm long, white to yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-3.8 mm long, green to pale pink. *Fruit* (14.4)15.5-17.6(18.6) mm long, erect, discharge of seed-ejection type; mericarps 2.8-3.6 mm long, 1.5-1.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.7 mm long; rostrum 9.2-12.5 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.3-0.7 mm long; stigmatic remnants 1.3-2.1 mm long, with 5 hairy lobes. *Seeds* 1.7-2.3 mm long, 1.3-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 277.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from October to March.

*Distribution*. This species ranges through New South Wales and Victoria, in southeastern Australia (Fig. 278).

*Habitat*. Grassy areas, gentle slopes, and edge of *Eucalyptus* L'Hér. forests; 1350-1550 m.

*Additional specimens examined*. **Australia**. AUSTRALIAN CAPITAL TERRITORY: Mt. Franklin, 35°28'S, 148°46'E, 3 Feb. 1961,

*Kaspiew* 1093 (L); Blackfellows Gap, Namadgi National Park, 2 km directly S of Mt. Gingera, 35°35'S, 148°46'E, 19 Jan. 1993, *Briggs & Zich* 2684 (NSW); Smokers' Flat Trail, S edge of Smokers' Flat, 3.5 km from carpak towards Orroral Valley turn-off, 36°1'S, 148°25'E, 6 Mar. 1993, *Zich* 223 (NSW). NEW SOUTH WALES: upper Tumur River near Junction Shaft, 36°1'S, 148°25'E, 16 Feb. 1957, *Filmer s.n.* (NSW); Kosciusko Hotel Dam, 36°24'S, 148°25'E, 24 Jan. 1959, *Carolin* 779 (K). VICTORIA: Point Lonsdale, 38°17'S, 144°37'E, Oct. 1912, *Tilden* 687 (F, G, GH, K).

*Discussion*. *Geranium obtusisepalum* is close to *G. retrorsum* and *G. solanderi*. The three species are erect, prostrate, or ascending perennial herbs with free stipules and short petals. They share a distinctive vertical, turnip-shaped rootstock, also found in some species from South America such as *G. core-core* and *G. limae* (Aedo & al. 2005a). *Geranium obtusisepalum* is well characterized by 1-flowered cymules and sepals with a very short mucro. Both *G. retrorsum* and *G. solanderi* have 2-flowered cymules and a conspicuous sepal mucro. The number of lobes of the middle leaf segment is always three in *G. obtusisepalum*, but varies from three to 10 in *G. retrorsum* and *G. solanderi*. *Geranium obtusisepalum* is more or less thickly covered with short, eglandular, usually spreading, hairs. Glandular hairs are also usually present and scattered among the eglandular hairs, but they are restricted to the stem and petiole base. *Geranium obtusisepalum* occurs in a small area in the mountains of southeastern Australia. A specimen collected by J.E. Tilden on Point Lonsdale on the coast of Victoria fits very well with *G. obtusisepalum*, although the locality far from the main range is rather surprising. Another outlier appears to be *Wehl s.n.*, 1892 (MEL) from southern Queensland (see Australia's Virtual Herbarium; <http://avh.chah.org.au>, 22 Nov, 2013). Unfortunately, I was unable to examine a voucher of the latter and have therefore not included it in the list of specimens examined or in the map.

**Discussion.** *Geranium grande* is a species easily recognizable by its turnip-shaped rootstock, robust stem, 2-flowered cymules, long peduncles, petals, and sepals, and fruit with a long narrowed apex and long persistent stigma lobes. It is interesting to note the significant gap in petal size between *G. solanderi*, which has petals that only reach a length of 8.5 mm long in extreme cases, and *G. grande*, which has petals that vary in length from 11.3 mm to 14.6 mm. The same pattern is found in the length of both the fruit narrowed rostrum apex and persistent stigma lobes of the fruit. It is curious that the distinctness of *G. grande* from *G. solanderi* has been overlooked by previous workers while other variability within *G. solanderi* has received considerable attention from a taxonomic point of view. Carolyn (1965: 353), in describing this variety, indicated that the rootstock is "swollen but not napiform." The holotype shows, however, a turnip-shaped rootstock indistinguishable from that of *G. solanderi*. *Geranium neglectum* resembles *G. grande* in its long peduncles, petals, and sepals, and fruit with a long narrowed rostrum apex and long persistent stigma lobes. *Geranium neglectum* is easily differentiated from *G. grande* by its 1-flowered cymules and cylindrical rootstock. A specimen at K collected by R.C. Carolyn from the Kosciusko Hotel has the same number (766) as the holotype. It appears that a labeling mistake has occurred, because the date (23 Jan. 1959) and the details of the locality are not those of the holotype.

Is., Waimea, 20°1'N, 155°39'W, 4 Apr. 1948, *Hosaka* 3590 (P); Maui Is., Pipe-line Trail, Olinda, 20°48'N, 156°16'W, 19 June 1927, *Degener* 18240 (GH, NY).

**Discussion.** *Geranium retrorsum* is characterized by a turnip-shaped rootstock, 2-flowered cymules with retrorsely appressed eglandular hairs on the peduncles and pedicels, and short petals. In addition, the rostrum of the fruits lacks a narrowed apex, or has a short narrowed apex only 0.4-1.2 mm long, and the persistent stigma lobes are short [(0.6)0.9-1.2(1.7) mm long]. *Geranium retrorsum* varies in degree of leaf dissection and has occasionally some 1-flowered cymules, especially toward the apex of the inflorescences. It is difficult to differentiate from forms of *G. solanderi* with "coarse hairs" where the indument of the peduncle and pedicel consists of more or less retrorse, but not appressed, hairs.

*Geranium geissei* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 70. 1912. TYPE LOCALITY: "Chile: Ohne genauere Standortangabe (Geisse -- Typus in herb. Berol.)". TYPE: Chile. [without locality], *R. Geisse s.n.* (holotype, B destroyed; photos, FI, GI, GHI, NY!). The holotype is no longer extant, and no duplicates were located. None of the Geisse collections at SGO can be associated with this name. The photographs of the holotype are not sufficiently detailed to permit accurate identification, but suggest that the name may be a synonym of *G. bertereanum*.

*Perennial herbs*, 13.5-59 cm tall. *Rootstock* 5.8-20.4 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.4-1.9 mm long and, sometimes, patent, glandular hairs 0.3-1.1 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae 1.8-9 cm long, 2.6-8.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.75)0.80-0.86], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces, sometimes glabrous adaxially; segments 5-7, in 1 plane, middle segment obtriangular, 1.8-10.6 mm wide at the base [ratio segment width at the base/middle segment length = (0.11)0.17-0.22(0.31)], 3-11-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.24-0.38(0.42)]; petioles up to 29.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.5-2 mm long and, sometimes, patent, eglandular hairs 0.3-0.9 mm long; stipules 4-9 mm long, 0.6-3 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 0.7-1.1(2.5)]; peduncles (8)17-45(58) mm long, with patent, eglandular hairs 0.2-1.2 mm long and, sometimes, patent, glandular hairs 0.3-1.1 mm long; bracteoles 2.5-6.7 mm long, 0.4-1.1 mm wide, linear-lanceolate, whorled; pedicels 9-27 mm long, with patent, eglandular hairs 0.2-1.2 mm long and, sometimes, patent, glandular hairs 0.3-1.1 mm long. Flowers actinomorphic. *Sepals* (4.4)5.4-6.1(7) mm long, 2-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.3)0.6-0.8(0.9) mm long [ratio mucro length/sepal length = (0.07)0.09-0.14(0.16)], with erect-patent, eglandular hairs

0.7-1.8 mm long and, sometimes, patent, glandular hairs 0.3-1.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (5.1)6.5-8(9) mm long, 2.5-4.5 mm wide, erect-patent, rounded or slightly emarginate, without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.5-4.5 mm long, lanceolate, white to yellow, with eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers 0.4-0.8 mm long, white to pink. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.9-5.2 mm long, white to pink. *Fruit* 11.4-24.6 mm long, erect, discharge of seed-ejection type; mericarps 2.3-4.2 mm long, 1.1-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-1.5 mm long and, sometimes, patent glandular hairs 0.2-0.8 mm long; rostrum 8.5-18.1 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.4-1 mm long and, sometimes, patent, glandular hairs 0.3-1.1 mm long; stigmatic remnants (1.1)1.3-1.7(2.1) mm long, with 5 hairy lobes. *Seeds* 1.3-3.1 mm long, 0.8-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 284, 285.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 7; Bortenschlager 1967: 425 [sub *G. patagonicum*]).

*Chromosome number*.  $2n = 52, 56, 84$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from central Chile and Argentina to southern Patagonia (Fig. 286).

*Habitat*. Roadsides, cultivated fields, dunes, meadows, river banks, dry slopes, shrublands, and *Acacia* Mill., *Araucaria* Juss., *Aristotelia* Lam. and *Nothofagus* Blume forests; 0-3800 m.

*Discussion.* *Geranium berterioanum* is a variable and widely distributed species; more than 2800 km separate the northernmost localities in central Chile from the southernmost in Tierra de Fuego. Some specimens have only eglandular hairs while others also have glandular hairs on stems, inflorescences, sepals, the rostrum of fruits, and/or mericarps. Usually

Fig. 286. Distribution of *Geranium berterioanum*.

*G. berterioanum* can be distinguished from *G. fallax* by its leaves with an obtriangular middle segment (rather than rhombic), and its fruit rostrum without a narrow apex. Yet, plants from central Argentina (provinces of Mendoza, San Juan, San Luis, and Córdoba) are difficult to assign to either *G. berterioanum* or *G. fallax*, especially herbarium specimens. During field work in this region populations were sampled to access variability but did not reveal absolute boundaries. In plants from the southwestern part of Argentina in Mendoza and San Juan a tendency for obtriangular leaves and a short narrow apex on the fruit rostrum is present, whereas plants from northeastern areas of San Luis and Córdoba are more similar to *G. fallax*, although the overlap is considerable. Therefore, some assignments of collections listed under *G. berterioanum* in Aedo & al. (2005a) are here listed as belonging to *G. fallax*: *Stuckert* 16629 (CORD), 1708, 12753 (S); the following collections were cited as *G. fallax* but are here listed as *G. berterioanum*: *Barklay s.n.*, 15 Jan. 1950 (NY), *Guaglianone & al.* 1479, 1497 (SI), *Kiesling & Megioli* 6680 (SI), *Paci* 781 (NY). Admittedly, the key provided in this account may not work very well in this area of contact; perhaps a future, more detailed study will provide a better one.

*Geranium skottsbergii*, also a species with eglandular and glandular variants, is partially sympatric with *G. berterioanum*, and can be distinguished by its longer petals and more deeply divided leaves. *Geranium solanderi* is endemic to Australia and New Zealand (and occasionally a garden-escape in California, U.S.A.), and strongly resembles *G. berterioanum* in its pedicels with patent hairs and many quantitative characters (petal length, sepal mucro length, etc.); however, *G. berterioanum* has longer bracteoles, sepals, and stigmatic remnants than *G. solanderi*.

*Geranium submolle* was described by Steudel (1856) based on *Bertero* 294, a heterogeneous collection. Most of specimens belong to *G. ber-*

*terioanum*, but some material of P and G is *G. skottsbergii* and thus excluded from the type material. Gay (1846) recorded *G. pyrenaicum* from Chile and noted that he had only one specimen in his herbarium. Marticorena & Quezada (1985) also listed *G. pyrenaicum* in their check-list for Chile. No new data about this species were provided by Aedo & al. (1998) in their revision of sect. *Batrachioidea*, since no specimen from Chile was available to them. The specimen supporting Gay's report was found at P (Colchagua, Feb. 1831, *Gay s.n.*) and identified as *G. berterioanum*, which refuted the reports of *G. pyrenaicum* in Chile (Aedo 2015). The proposal by Stuessy & Marticorena (1990) to correct the orthography of epithets honouring Bertero is here followed.

---

TYPE LOCALITY: "Tambo bei Mollendo, auf Felsen in der Loma-Formation zwischen 400-600 m (Weberbauer n. 1579). - Blühend und fruchtend im Oktober". TYPE: Peru. Arequipa, Tambo, Mollendo, 17°01'S, 72°00'W, A. Weberbauer 1579 (no original material located).

*Perennial herbs*, 8-55 cm tall. *Root-stock* 8.7-24.4 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, not appressed, eglandular hairs 0.5-1.2 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminas 1.3-5.5 cm long, 1.7-6.6 cm wide, not peltate, palmatifid [ratio

main-sinus length/middle segment length = 0.70-0.80], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment obtriangular, 3.6-9 mm wide at the base [ratio segment width at the base/middle segment length = (0.20)0.24-0.32(0.42)], 3-11-lobed in distal half [ratio secondary sinus length/middle segment length = (0.14)0.24-0.29(0.34)]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, appressed, eglandular hairs 0.5-1.4 mm long; stipules 2.5-9 mm long, 0.7-3.4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 0.4-0.9(2.9)]; peduncles (11)20-37(68) mm long, with patent to retrorse, eglandular hairs 0.4-1.6 mm long; bracteoles 2-5.9 mm long, 0.5-1.9 mm wide, linear-lanceolate, whorled; pedicels 7-22 mm long, with patent to retrorse, eglandular hairs 0.4-1.6 mm long. Flowers actinomorphic. *Sepals* (3.5)4.5-5.5(6.3) mm long, 1.7-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.2)0.3-0.4(0.5) mm long [ratio mucro length/sepal length = (0.03)0.05-0.07(0.09)], with erect-patent, eglandular hairs 0.3-1.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (5)5.6-7.5(8.2) mm long, 2-4.6 mm wide, erect-patent, rounded, without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.6-4.9 mm long, lanceolate, yellow, with eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers 0.4-0.8 mm long, yellow. Nectaries 5, hemispheric, usually with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3-5 mm long, pink. *Fruit* 11-21.1 mm long, erect, discharge of seed-ejection type; mericarps 2.7-3.5

mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-1.1 mm long; rostrum 7.5-15.4 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.3-1.3 mm long; stigmatic remnants 1.1-

1.5(1.8) mm long, with 5 hairy lobes. Seeds 1.8-2.5 mm long, 1.1-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 287.

*Pollen.* *Geranium*-type (Aedo & al. 2005a: 6).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from January to November.

*Distribution.* This species ranges through western Peru (Fig. 288).

*Habitat.* Coastal desert, hillsides with scattered shrubs, on sandy or clayed soils, sometimes in rock crevices; 0-3100 m.

*Additional specimens examined.* **Peru.**

**Discussion.** *Geranium limae* shares with *G. albicans* and *G. berterioanum* patent hairs on peduncles and pedicels. The differences between *G. limae* and *G. albicans* are indicated under *G. albicans*; their ranges are completely allopatric. *Geranium limae* has shorter sepals with a shorter mucro than *G. berterioanum*, and it also has longer hairs on the rostrum than *G. berterioanum*. The base of the middle segment is wider in *G. limae* than in *G. berterioanum*, and the main sinus of the middle segment is not as deep as in *G. berterioanum*, which gives a less deeply divided appearance to leaves of *G. limae*. The nectaries of *G. limae* usually have a tuft of hairs at the apex but are always glabrous in *G. berterioanum*. Glandular hairs are always absent in *G. limae* but may be present in *G. berterioanum*.

Knuth (1912) noted, erroneously, that Gaudichaud collected the origi-

nal material of *G. limae* in 1841. Gaudichaud acted as botanist to the *La Bonite* expedition during its circumnavigation of the globe in 1836-1837, and the label of the type specimen clearly states "Juillet 1836." Knuth (1906) based his *Geranium multiflorum* on a Weberbauer collection from southern Peru. Although the holotype is lost, the presence of 2-flowered cymules and patent, eglandular hairs on pedicels noted in the original description indicates *G. multiflorum* is conspecific with *G. limae*.

**108. *Geranium albicans*** A. St.-Hil., Fl. Bras. Merid. 1: 83. 1825. TYPE LOCALITY: "Inveni Septembre propè praedium Giribatubà, provinciâ Rio Grande do Sul; et December, propè vicum S. *Discussion.* *Geranium albicans* is characterized by its peduncles and pedicels with eglandular patent hairs, short petals, and a short sepal mucro. The leaves are densely hairy, and the main leaf segment is rhombic in outline. *Geranium albicans* is sometimes confused with eglandular forms of *G. berterioanum*, which has longer petals and obtriangular main leaf segments, as well as a longer sepal mucro and shorter hairs on peduncles and pedicels. *Geranium corecore*, a sympatric species, has shorter hairs on the stems, relatively wider sepals, and retrorse-appressed hairs on pedicels.

**109. *Geranium magellanicum* Hook.** f., Fl. Antarct. 2: 251. 1845. TYPE LOCALITY: "Hab. Strait of Magalhaens, Elisabeth Island; C. Darwin, Esq.". TYPE: Chile. Strait of Magalhaens, Elisabeth Island, 52°52'S, 70°43'W, *C. Darwin s.n.* (lectotype, designated by Porter 1999: 196, K!).

*Perennial herbs*, 8-34 cm tall. *Rootstock* 5.9-14.1 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, appressed, eglandular hairs 0.3-1.4 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae 1.1-4.3 cm long, 1.3-4.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.51)0.76-0.86], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment obtriangular, 1.9-5.2 mm wide at the base [ratio segment width at the base/middle segment length = (0.10)0.17-0.23(0.28)], 3-9-lobed in distal half [ratio secondary sinus length/middle segment length = (0.17)0.25-0.34(0.45)]; petioles up to

14 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, appressed, eglandular hairs 0.4-1.4 mm long; stipules 3.6-10.5 mm long, 0.9-3 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary (cymules of the basal part of the stem usually 1-flowered, a part of them arise directly from the rootstock, and cymules of the upper part 2-flowered) [ratio cymule length/leaf length = (0.4)1-2.5]; peduncles (13)28-40(69) mm long, with patent to retrorse, appressed, eglandular hairs 0.5-1.2 mm long; bracteoles 3.1-7.2 mm long, 0.6-1.8 mm wide, linear-lanceolate, whorled; pedicels 5.4-48.9 mm long, with patent to retrorse, appressed, eglandular hairs 0.5-1.2 mm long. Flowers actinomorphic. *Sepals* 4.7-6(6.5) mm long, 1.9-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.2)0.4-0.5(1) mm long [ratio mucro length/sepal length = (0.03)0.07-0.10(0.16)], with erect-patent, eglandular hairs 0.4-1.9 mm long (usually the longest on the margin) on the abaxial surface, glabrous adaxially. *Petals* (3.9)6.2-8(11.7) mm long, 2-5.4 mm wide, erect-patent, rounded, without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.2-4.3 mm long, lanceolate, white to yellow, with eglandular hairs 0.2-0.5 mm long on the abaxial surface and margin; anthers 0.4-1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.9-5 mm long, pink. *Fruit* 15.3-22.2 mm long, erect, discharge of seed-ejection type; mericarps 3-4 mm long, 1.4-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-1.3 mm long; rostrum 10.4-16.5 mm long, without a narrowed apex,

not twisted, with erect-patent, eglandular hairs 0.2-0.7 mm long; stigmatic remnants (1)1.3-1.7(2.1) mm long, with 5 hairy lobes. *Seeds* 2-2.6 mm long, 1.2-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 291, 292.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 6; Bortenschlager 1967: 425).

*Chromosome number*.  $2n = 112$ .

*Phenology*. Collected in flower from November to April.

*Distribution*. This species ranges from central Chile and Argentina to Patagonia (Fig. 293).

*Habitat*. Cultivated fields, bogs with *Acaena* L. or *Gunnera* L., open grassy slopes, and *Nothofagus* Blume and *Araucaria* Juss. forests; 0-1200 m.

*Representative specimens examined*.

**Discussion.** *Geranium magellanicum* is easily recognized by its ascending habit and by its unusual inflorescence arrangement. The cymules at the basal part of the stem are usually 1-flowered, and some of them arise directly from the rootstock. The cymules are 2-flowered on the middle and distal portions of the stems. This inflorescence structure suggests that *G. magellanicum* may be allied with *G. sessiliflorum*; however, that species never has 2-flowered cymules. Additionally, *G. magellanicum* has longer fruits and rostra, peduncles, and pedicels than are found in *G. sessiliflorum*; the hairs composing the pedicel indumentum are also longer. The indumentum of *G. magellanicum* on stems, petioles, peduncles, and pedicels varies from patent to retrorse-appressed, but no specimens with glandular hairs were seen. Moore (1983) listed *G. patagonicum* as a synonym of *G. magellanicum*, and thus noted that *G. magellanicum* can have glandular hairs. Barboza & Correa (1988) and Barboza (1996) excluded glandular specimens from *G. magellanicum*, as is done here. *Geranium berterianum* (including *G. patagonicum*) can be easily differentiated from *G. magellanicum* by its erect to ascending stems with only 2-flowered cymules and by the longer sepal mucro. Barboza (1996) recognized *G. magellanicum* var. *pumilum*, which is here included in *G. parodii*; see that species.

Fig. 295. *Geranium skottsbergii* (Based on: a-d, Calvo 7807, SGO, photo: J. Calvo; e, f, Aedo 6821, MA).

*Discussion.* *Geranium skottsbergii* is easily recognized by its deeply divided leaves with narrow lobes and relatively long petals. Some specimens have only eglandular hairs on stems, petioles, and pedicels; these hairs are sometimes retrorse and appressed, sometimes more or less patent. Some specimens have particularly long hairs on the sepal margin. Plants with glandular and eglandular hairs occur over the entire range of this species. *Geranium skottsbergii* is endemic to central Chile, where it could be confused with *G. berteroa-num*, which has shorter petals and less divided leaves. *Geranium core-core*, which is also present in this region, has less divided leaves than *G. skottsbergii*, stems with shorter hairs, a shorter gynoecium, and relatively wider sepals.

*Perennial herbs*, 15-75 cm tall. *Rootstock* 4-18.1 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminas (1.5)1.9-3.9(4.7) cm long, 1.7-5.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.57)0.74-0.85], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, (1.9)2.7-4.9(8.5) mm wide at the base [ratio segment width at the base/middle segment length = (0.14)0.18-0.27(0.32)], 3-11-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.25-0.37(0.39)]; petioles up to 17 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules 3.5-8.2 mm long, 0.5-2.5 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/

leaf length = (0.5)1-2.4]; peduncles (6)13-28(51) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long; bracteoles 2-4.5 mm long, 0.4-0.9 mm wide, linear-lanceolate, whorled; pedicels (11)14-18(31) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* 3-4.2(5.5) mm long, 2-4.3 mm wide, ovate, smooth, accrescent, nerves 3, mucro (0.4)0.6-0.9(1.1) mm long [ratio mucro length/sepal length = (0.07)0.13-0.20(0.32)], with antrorse,  $\pm$  appressed, eglandular hairs 0.1-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (3.1)4.1-6(7.1) mm long, (1.7)2.2-2.9(3.5) mm wide, erect-patent, rounded or emarginate, without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments (1.8)2.6-2.9(3.7) mm long, lanceolate, white, glabrous on the abaxial surface, ciliate on the basal margin, with hairs up to 0.1-0.2 mm long; anthers (0.3)0.4-0.6(0.8) mm long, white to pink. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.3-4 mm long, white. *Fruit* (9.5)15-17(19) mm long, erect, discharge of seed-ejection type; mericarps 2.6-3.2 mm long, 1.2-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-1.4 mm long; rostrum 9.1-14.5 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.7 mm long; stigmatic remnants (0.9)1.1-1.2(1.5) mm long, with 5 hairy lobes. *Seeds* 1.8-2.9 mm long, 1-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 297, 298.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 7).

*Chromosome number*.  $2n = 56$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from Ecuador to southern Argentina

and it is introduced in southwestern U.S.A. and Europe (Great Britain) (Fig. 299).

*Habitat*. Roadsides, cultivated ground, beaches, grassy hillsides, along water courses, shrublands, *Myrceugenia* O. Berg and *Nothofagus* Blume forests; 0-4000 m.

**Discussion.** *Geranium core-core* is readily distinguished by its peduncles and pedicels with retrorse-appressed, eglandular hairs, by its shallowly divided leaves, and short petals. It resembles *G. retrorsum*, a species of Australia and New Zealand, which differs most noticeably in sepal shape; *G. retrorsum* has lanceolate sepals, whereas *G. core-core* has broadly ovate sepals. Additionally, *G. core-core* has longer fruits with a longer rostrum than is found in *G. retrorsum*. Two sheets of the type collection, *Bertero* 1018, are kept at G. One is *G. core-core* and the other *G. skottsbergii*. According to the typification proposed by Aedo (2004: 1074) the first is an isolectotype of *G. core-core*, and the second is excluded. *Geranium rapulum* was published fourteen

years before *G. core-core*, but it was never taken up, whereas *G. core-core* has been used in many floristic publications about Chile and Argentina. The proposal (Aedo 2004) to conserve the name *G. core-core* over *G. rapulum* was accepted at the Botanical Congress in Vienna in 2006.

*Geranium core-core* is a South American species introduced in California and Europe. It has been established in Channel Islands and southern England where it has been identified as *G. potentilloides* and/or *Geranium submolle*, a synonym of *G. berteroanum* (Townsend 1964), or as *G. retrorsum* (Kent 1959; Lousley 1962). Yeo (2002b) tentatively used the name *G. herrerae* for this weed, a synonym of *G. core-core*.

**112. *Geranium tablasense*** R. Knuth, Meded. Rijks-Herb. 27: 68. 1915. TYPE LOCALITY: "Im Gebüsch der Waldgrenze über Tablas, 3400 m (no. 2181, bl. u. fr. im Mai 1911.-Typus!)". TYPE: Bolivia. Cochabamba, Tablas, 17°05'S, 65°59'W, May 1911, *T. Herzog* 2181 (lectotype, designated by Aedo & al. 2005a: 53, L-0018356!; isolectotype, S-R-2402!).

*Perennial herbs*, 37-55 cm tall. *Root-stock* 8-8.2 mm in diameter, vertical, not tuberculate, turnip-shaped, with thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, not appressed, eglandular hairs 0.3-1.2 mm long and patent, glandular hairs 0.4-0.9 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminae 3.6-5.4 cm long, 5.1-6.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.52-0.61], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs (young leaves sericeous abaxially) on both surfaces; segments 5-7, in 1 plane, middle segment rhombic, 3.2-4.6 mm wide

at the base [ratio segment width at the base/middle segment length = 0.09-0.12(0.14)], 10-14-lobed in distal half [ratio secondary sinus length/middle segment length = (0.24)0.27-0.37(0.42)]; petioles up to 8.2 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-1.3 mm long; stipules 7.5-9.8 mm long, 2.7-3.2 mm wide, lanceolate, free, papery, brownish red, glabrous or with scattered, eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 0.7-2.8]; peduncles (37)40-70(80) mm long, with patent to retrorse, not appressed, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.4-0.9 mm long; bracteoles 2.5-6.7 mm long, 0.6-1.8 mm wide, lanceolate, whorled; pedicels 28-46 mm long, with patent to retrorse, not appressed, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.4-1.3 mm long. Flowers actinomorphic. *Sepals* 7.4-8 mm long, 2.4-3.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-1.3(1.4) mm long [ratio mucro length/sepal length = (0.09)0.10-0.16(0.17)], with erect-patent, eglandular hairs 0.5-1.4 mm long and patent, glandular hairs 0.4-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (11.4)13.4-16.4(16.9) mm long, 7.4-8.2 mm wide, erect-patent, emarginate (notch 1.5-1.9 mm deep), with claw 1-3.5 mm long, purple, glabrous, rarely sparsely ciliate on the basal margin, with hairs 0.2-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.5-8 mm long, lanceolate, yellow, glabrous on both surfaces, ciliate on the basal margin, with hairs up to 0.1-0.2 mm long; anthers 1.1-1.8 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 7-8.2 mm long, unknown color. *Fruit* 24.2-27.7 mm long, erect, discharge of seed-ejection type; mericarps 3.2-4 mm long, 1.6-1.8 mm wide, without a strand of

fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.9 mm long; rostrum 17-21.1 mm long, with a narrowed apex (2)2.3-3.8(5) mm long, not twisted, with erect-patent, eglandular hairs 0.4-0.9 mm long; stigmatic remnants (2.6)2.8-3.4(3.8) mm long, with 5 glabrous lobes. *Seeds* 2.1-2.2 mm long,

1.1-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 300.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 7).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to May.

*Distribution*. This species ranges through central Bolivia (Fig. 301).

*Habitat*. Rocky and wet slopes; 2800-3700 m.

*Additional specimens examined*. **Bolivia**. COCHABAMBA: km 80 road to Chimoré-Cochabamba, 16°59'S, 65°7'W, Apr. 1939, *Cárdenas* 758 (US); bei km 94 der strasse Cochabamba-Todos Santos, 17°12'S, 65°43'W, 22 Apr. 1959, *Diers* 870 (P); Incachaca, 17°14'S, 66°28'W, Mar. 1941, *Cárdenas* 2180 (GH, PH, S, U); Chapare, road from Aguirre to Incachaca, taking left hand turning 2.5 km, and 16.5 km from Aguirre, 17°20'S, 65°46'W, 10 Mar. 1929, *Hawkes & al.* 6680 (C); Chapare, La Aduana, 17°32'S, 65°13'W, 10 Mar. 1929, *Steinbach* 9576 (BM, E, F, G, GH, MO, NY, PH, S, U).

*Discussion*. *Geranium tablasense* shares with *G. venturianum* and *G. fallax* leaves with rhombic segments and a fruit rostrum with a narrowed apex. It can be distinguished by its longer petals, which show some overlap with *G. venturianum* but not with *G. fallax*. Additionally, the petals of *G. tablasense* are glabrous or rarely with few cilia at the basal margin, whereas the petals are hairy at the basal margin in *G. venturianum* (and at base of abaxial surface) and *G. fallax*. *Geranium venturianum* has longer peduncles, shorter staminal filaments, and a rostrum with a shorter narrowed apex than is found in *G. tablasense*. *Geranium tablasense* differs also in having basal leaves with narrow segments and longer fruits than do *G. venturianum* and *G. fallax*.

**Discussion.** *Geranium venturianum* is distinctive in its long peduncles, which decrease in length towards the apex of the inflorescence; in the description of *G. venturianum* and in the key peduncles of the basal part of the inflorescence are emphasized. Although a small overlap in peduncle length exists between *G. venturianum* and *G. tablasense*, length of petals, staminal filaments, fruit, and rostrum apex permit a ready separation of the species. *Geranium venturianum* varies in the presence of glandular hairs; some specimens only have eglandular hairs, but others have also glandular hairs on stems, inflorescences, sepals, fruit rostra, and/or mericarps. These glandular forms have been occasionally misidentified as "*G. fiebrigianum*" (here listed as a synonym of *G. fallax*) or "*G. patagonicum*" (here listed as a synonym of *G. berterioanum*). *Geranium venturianum* can be distinguished from *G. berterioanum* by its leaves with a rhombic (rather than obtriangular) middle segment and its fruit rostrum with a narrow apex. The best way to distinguish *G. venturianum* from *G. fallax* is by the length of the peduncles, which are clearly longer in *G. venturianum*. Additionally, in *G. venturianum* the fruits (including the narrow apex of the rostrum), stigmatic remnants, bracteoles, sepals, and petals are

*Discussion.* *Geranium fallax* resembles *G. venturianum* and *G. tablasense*, but unlike these species always has glandular hairs, sometimes restricted to pedicels, sepals, and fruits, but usually spread all over the inflorescence and stem. In *G. fallax* the petals are shorter than in the other two species and glabrous on both surfaces, with cilia on the basal margin; they are glabrous in *G. tablasense*, and hairy on the margin and abaxial base in *G. venturianum*. Additionally, *G. fallax* the narrowed apex of the fruit rostrum is shorter than in *G. venturianum* and *G. tablasense*. Specimens are occasionally misidentified as "*G. patagonicum*" [= *G. berterioanum*], which has leaves with obtriangular (not rhombic) segments. For a detailed discussion of differences between *G. fallax* and *G. berterioanum*, see that species.

*Geranium totorense* was based on a Steinbach collection from Cochabamba, Bolivia, which is now lost. According to the original description the specimen had glandular hairs on the inflorescence, rhombic leaves, and petals ca. 10 mm long; however, the number of flowers per cymule is not noted. These details and the type locality suggest that *G. totorense* is a synonym of *G. fallax*. The type collection for *G. bolivianum* is heterogeneous. The sheets at BM, F, GH, K, NY, P, and US are *G. fallax*, and the P sheet is here chosen as lectotype, but duplicates at MO, NY, and W have 1-flowered cymules without glandular hairs and belong to *G. so-ratae*. This typification is in accordance with the original description.

**The Sessiliflorum Group**—This group is characterized by its scapiform, cushion-like habit, its turnip-shaped rootstock, its eglandular indumentum, and its 1-flowered cymules arising usually directly from the rootstock, sometimes lacking pedicels. The leaves are palmatifid and the petals are usually of small size and without claw.

**115. *Geranium antrorsum*** Carolin, Proc. Linn. Soc. New South Wales ser. 2, 89: 357, pl. 6 fig. 14, pl. 7 fig. 10. 1965. TYPE LOCALITY: "Kosciusko Hotel dam, R. Carolin No. 778b, 24.1.1959 (NSW 66132)". TYPE: Australia. New South Wales, Kosciusko Hotel, 36°24'S, 148°25'E, 24 Jan. 1959, *R.C. Carolin* 778b (holotype, NSW-66132; isotype, K!).

*Perennial herbs*, 5.5-20 cm tall. *Rootstock* 3.9-11.6 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* scapiform, stolons absent, without vegetative stems. *Basal leaves* in a persistent rosette; leaf laminas (0.9)1.6-2.7(3.3) cm long, 1.3-4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.56-0.68], polygonal in outline, base cuneate to subtruncate (with basal leaf segments patent or upward), not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 2.3-6.8 mm wide at the base [ratio segment width at the base/middle segment length = (0.15)0.18-0.29], 3-5(7)-lobed at the apex [ratio secondary sinus length/middle segment length = (0.13)0.15-0.18(0.21)]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to antrorse, appressed, eglandular hairs 0.3-1.6 mm long; stipules 5.7-14.4 mm long, 1.2-3.5 mm wide, lanceolate, free, papery, brownish red, with

eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = (0.1)0.2-0.4(0.6)]; peduncles 4-12(21) mm long, with antrorse, appressed, eglandular hairs 0.2-1 mm long; bracteoles 3.5-7.1 mm long, 0.8-1.5 mm wide, lanceolate, opposite; pedicels absent

or 6.5-37 mm long, with antrorse, appressed, eglandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* (4.3)5.1-6.4(8.2) mm long, 1.7-3.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.2)1.3-1.9(2.9) mm long [ratio mucro length/sepal length = (0.20)0.23-0.36(0.45)], with erect-patent, eglandular hairs 0.5-

0.8 mm long on the abaxial surface (patent hairs 1-1.4 mm long on the margin), glabrescent adaxially. *Petals* (3.6)4.1-7.4(9.2) mm long, 1.2-4.4 mm wide, erect-patent, rounded, without claw, purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.4-3.6 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.3 mm long; anthers 0.6-0.9 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.5-4 mm long, purple. *Fruit* 13.9-16.5 mm long, erect, discharge of seed-ejection type; mericarps 2.6-3.9 mm long, 1.3-1.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.8 mm long; rostrum 9-10.6 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.2-0.9 mm long; stigmatic remnants (1)1.4-1.7(2.2) mm long, with 5 hairy lobes. *Seeds* 2-2.9 mm long, 1.2-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 308.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 7).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from December to April.

*Distribution*. This species ranges through New South Wales and Victoria, in southeastern Australia (Fig. 309).

**Discussion.** *Geranium antrorsum* is a stemless species with a vertical rootstock that is short branched at the apex. The leaves are arranged in a rosette and overtop the cymules. The 1-flowered cymules are borne on the rootstock. On the same individual a pair of bracteoles divide the peduncle from the pedicel on some cymules, but peduncles without bracteoles also occur. *Geranium antrorsum* is easily recognized by the patent or upwardly oriented basal leaf segments, giving a cuneate to subtruncate aspect to the leaf, and by the antrorsely appressed eglandular hairs of the peduncles and pedicels. It has usually been considered to be closely related to *G. brevicale* and *G. sessiliflorum*. Those species, however, have cordate leaves and pedicels with patent to retrorse hairs. In addition, *G. antrorsum* has sepals with a mucro 1.2-2.9 mm long, which shows some overlap with *G. brevicale* (mucro 0.4-1.9 mm long), but no overlap with *G. sessiliflorum* (mucro 0.3-1.1 mm long).

**Perennial herbs**, 2.5-15.5 cm tall. **Rootstock** 3.2-10.5 mm in diameter, vertical, not tuberculate, usually turnip-shaped, without thickened roots. **Stem** scapiform, cushion-like, stolons absent, without vegetative stems. **Basal leaves** in a persistent rosette; leaf laminae (0.7)1-1.7(2.5) cm long, 0.8-3.1 cm wide, not peltate, palmat-

ifid [ratio main-sinus length/middle segment length = 0.70-0.76], polygonal in outline, base cordate (with basal leaf segments downward), not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 1.1-4.7 mm wide at the base [ratio segment width at the base/middle segment length = (0.19)0.24-0.35(0.42)], 3-7-lobed in distal half [ratio secondary sinus length/middle segment length = (0.10)0.21-0.26(0.35)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, appressed, eglandular hairs 0.3-1.2 mm long; stipules 2.7-8.8 mm long, 0.9-2.5 mm wide, lanceolate, free, papery, brownish red, with scattered, eglandular hairs on both surfaces and on the margin. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.14-1]; peduncles 3-11(16) mm long, with patent to retrorse, eglandular hairs 0.1-1.1 mm long; bracteoles 2-6.5 mm long, 0.6-1.2 mm wide, lanceolate, opposite; pedicels absent or 3.3-43 mm long, usually with patent to retrorse, eglandular hairs 0.1-1.1 mm long. Flowers actinomorphic. *Sepals* (3.3)4.4-5.7(7.1) mm long, 1.4-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.4)0.9-1.3(1.9) mm long [ratio mucro length/sepal length = (0.14)0.20-0.26(0.38)], with erect-patent, eglandular hairs 0.3-0.6 mm long on the abaxial surface (patent hairs 1-1.7 mm long on the margin), glabrescent adaxially. *Petals* 2.8-5.5(6.5) mm long, 1-3.1 mm wide, erect-patent, rounded, without claw, deep pink to white, glabrous, rarely sparsely ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.6-3 mm long, lanceolate, yellow, glabrous on the abaxial surface, ciliate on the basal margin, with hairs 0.1-0.2 mm long; anthers 0.4-0.7 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2-3.4 mm long, unknown color. *Fruit* 8.4-17.6 mm

long, erect, discharge of seed-ejection type; mericarps 2.2-4.1 mm long, 1-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-1.1 mm long; rostrum 5.1-11.7 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.6 mm long;

stigmatic remnants 0.9-1.2(1.6) mm long, with 5 hairy lobes. *Seeds* 1.5-2.8 mm long, 0.7-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 310.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 7).

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from January to December.

**Discussion.** *Geranium brevicaule* is quite similar to *G. antrorsum* in general appearance. Both species share a stemless habit, a rosette of leaves longer than the cymules, cymules borne on the rootstock and a relatively long sepal mucro. However, *G. brevicaule* can be easily distinguished by its pedicels with patent to retrorse hairs (antrorse hairs in *G. antrorsum*), and by the downwardly oriented basal leaf segments (patent or upwardly oriented in *G. antrorsum*). In addition, *G. antrorsum* has a longer gynoeceum and rostrum than *G. brevicaule*. *Geranium sessiliflorum* is a very variable species with a large geographical distribution in South America, and includes most of the differentiating characters proposed for *G. brevicaule*. Two quantitative characters, however, permit differentiation of the species, although with some overlap. The petals of *G. brevicaule* are shorter than in *G. sessiliflorum*, and the sepal mucro of *G. brevicaule* is longer than in *G. sessiliflorum*. The ratio of mucro length to sepal length also supports this difference. *Carolin* (1965: 356) considered *G. sessiliflorum* to include two subspecies, one endemic to New Zealand and the other restricted to southeastern continental Australia and Tasmania. He distinguished subsp. *novazelandiae* by the long hairs of the sepals tending to be inserted toward the margin (also on the abaxial surface on subsp. *brevicaule*), the relatively shorter sepal mucro (ca. 1 mm long in subsp. *novazelandiae*, 1 mm or longer in subsp. *brevicaule*), and longer petals (c. 1.5 times as long as the sepals in subsp. *novazelandiae* and shorter than to slightly exceeding the sepals in subsp. *brevicaule*). On the studied material I was not able to find any difference in sepal indument or mucro length between plants from Australia (including Tasmania) and from New Zealand. Petals of New Zealand plants are sometimes slight-

ly longer than on those in Australian specimens, but great overlap was found in this character. Thus, I prefer to include all these plants within a single taxon that can be more consistently distinguished from the South American *G. sessiliflorum*.

**117. *Geranium cruentum*** Heenan & G.M. Rogers, New Zealand J. Bot. 59: 9, 6 fig.2. 2021. TYPE LOCALITY: "NEW ZEALAND. Canterbury, Lincoln, Landcare Research experimental nursery, 2 November 2013, P. B. Heenan s.n. (holotype: CHR 641111; isotypes: AK, CHR 641112, WELT)". TYPE: New Zealand. South Is., cultivated at Canterbury, Lincoln, Landcare Research experimental nursery from Von River valley, 45°09'S, 168°17'E, 2 Nov. 2013, *P.B. Heenan s.n.* (holotype, CHR-641111 image!; isotypes, AK, CHR-641112, WELT).

*Perennial herbs*, 7-11 cm tall. *Rootstock* 7.1-8.6 mm in diameter, vertical, not tuberculate, usually turnip-shaped, without thickened roots. *Stem* prostrate to decumbent, scapiform, cushion-like, not rooting at nodes, stolons absent, without vegetative stems. *Basal leaves* in a persistent rosette; leaf laminas 1.1-1.3(2) cm long, 1.3-1.6(2.3) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.66-0.87], polygonal in outline, base cordate (with basal leaf segments downward), not coriaceous, with nerves not projected, sparsely to moderate hairy, with eglandular hairs on both surfaces (glabrous or with hairs restricted to nerves abaxially); segments 5, in 1 plane, middle segment elliptic to obovate, 2.2-3.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.31-0.34], entire, rarely 2-3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.10-0.24]; petioles up to 12.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular

Fig. 311. Distribution of *Geranium brevicaule*.

hairs 0.1-0.5 mm long; stipules 4-12 mm long, 1.2-6.5 mm wide, lanceolate, free, papery, pale-pink, glabrous. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.7-0.8]; peduncles 10-24 mm long, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long; bracteoles 3.8-4.8 mm long, 0.6-0.8 mm wide, lanceolate, opposite; pedicels absent or 17-26 mm long,

with retrorse, appressed, eglandular hairs 0.2-0.3 mm long. Flowers actinomorphic. *Sepals* 4.2-6.6 mm long, 2-3.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.3-1.5 mm long [ratio mucro length/sepal length = 0.2-0.3], with appressed, eglandular hairs 0.1-0.8 mm long on the abaxial surface (patent hairs 0.7-1.7 mm long on the margin), glabrescent

adaxially. *Petals* 4.6-7.4 mm long, 2.3-3.8 mm wide, erect-patent, rounded, without claw, white, with pink veins, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.5-3.5 mm long, lanceolate, white, glabrous or ciliate on the basal margin, with hairs 0.1-0.2 mm long; anthers 0.4-0.6 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.1-4 mm long, white. *Fruit* 11.8-13 mm long, erect, discharge of seed-ejection type; mericarps 2.4-2.6 mm long, 1.1-1.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.5 mm long; rostrum 7-9 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 1.2-1.4 mm long, with 5 hairy lobes. *Seeds* 1.8-2.2 mm long, 1.2-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 312.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower in November.

*Distribution*. This species is endemic to southern New Zealand (Fig. 313).

*Habitat*. Probably in wetlands.

*Additional specimens examined*. **New Zealand**. NEW ZEALAND SOUTH IS.: cultivated at Pohara, Golden Bay, from Von River valley, 45°9'S, 168°17'E, 18 Nov. 2001, Courtney s.n. (CHR); cultivated from Von

Fig. 313. Distribution of *Geranium cruentum*.

River valley, 45°9'S, 168°17'E, Oct. 2007, *de Lange* 9220 (CHR).

**Discussion.** *Geranium cruentum* is quite similar to *G. brevicaulis* with its scapiform, cushion-like habit and 1-flowered cymes. However, it is easily differentiated by its leaves which have elliptic to obovate segments, usually entire, darkly spotted below the primary sinus. According to Heenan & Rogers (2021) this species "is known from a single collection that was unknowingly made in the Von River valley, Southland. Repeated searching at the original site has not located any additional plants". In the protologue the type and other four additional collections are mentioned, all from cultivated origin.

**Perennial herbs**, 2.2-8.9 cm tall. **Rootstock** 2.8-18.9 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. **Stem** prostrate (when present), usually scapiform, cushion-like, not rooting at nodes, stolons absent, without vegetative stems. **Basal leaves** in a persistent rosette, cauline leaves usually absent, sometimes 1(2) pairs, opposite; leaf laminae (0.7)1.2-1.8(2.7) cm long, 0.8-3.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.64-0.92], orbicular to polygonal in outline, base cordate (with basal leaf segments downward), not coriaceous, with nerves not projected, glabrescent to pilose (sometimes densely) on both surfaces, with appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic to obtriangular, 0.6-4.1 mm wide at the base [ratio segment width at the base/middle seg-

ment length =  $(0.08)0.15-0.23(0.35)$ ], 3-12-lobed in distal half [ratio secondary sinus length/middle segment length =  $(0.21)0.28-0.36(0.54)$ ]; petioles up to 8 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, appressed, eglandular hairs 0.2-1.7 mm long; stipules 5.5-15.8 mm long, 0.8-3.1 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 1-flowered, solitary (rarely in aggregates) [ratio cymule length/leaf length = 0.1-0.8]; peduncles 1-5(14) mm long, with retrorse, appressed, eglandular hairs 0.3-1 mm long; bracteoles 5-6.1 mm long, 1-1.65 mm wide, linear-lanceolate, opposite; pedicels absent or 4-42 mm long, usually with retrorse to patent (rarely antrorse), appressed, eglandular hairs 0.3-1.2 mm long. Flowers actinomorphic. *Sepals*  $(3.8)4.7-6.2(7.1)$  mm long, 1.4-3.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro  $(0.3)0.4-0.7(1.1)$  mm long [ratio mucro length/sepal length =  $(0.04)0.07-0.15(0.19)$ ], with erect-patent, eglandular hairs 0.3-0.6 mm long on the abaxial surface (patent hairs 0.9-2.8 mm long on the margin), glabrescent adaxially. *Petals*  $(4.5)6-12.8$  mm long, 1.6-5 mm wide, erect-patent, rounded, rarely emarginate (notch 1 mm deep), without claw, purple, sometimes white, glabrous, rarely sparsely ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.1-4.6 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 0.5-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.9-5 mm long, yellow. *Fruit* 6.8-19.5 mm long, erect, discharge of seed-ejection type; mericarps 1.8-4.5 mm long, 0.9-2.25 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.6 mm long; rostrum 4.1-13 mm long,

without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.2-1.2 mm long; stigmatic remnants  $(0.8)1-1.5(2)$  mm long, with 5 glabrous lobes. *Seeds* 1.1-3.3 mm long, 0.9-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 314, 315.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 6; Bortenschlager 1967: 425).

*Chromosome number*.  $2n = 52, 56$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from central Peru to southern Chile and southern Argentina (Fig. 316).

*Habitat*. Roadsides, beaches, river banks, turf bogs, open rocky slopes, meadows, open moist puna sometimes with low shrubs, and clearing in *Nothofagus* Blume and *Polylepis* Ruiz & Pav. forests; 0-5000 m.

**Discussion.** *Geranium sessiliflorum* usually forms dense cushion plants. It has a vertical, turnip-shaped rootstock and sepals with long, patent hairs on the margins (more or less pectinate). It is distributed over a large area with more than 5000 km between the northernmost localities in central Peru and the southernmost in Tierra del Fuego. Although *G. magellanicum* is quite similar to *G. sessiliflorum*, it is easily distinguished

by its 2-flowered cymules borne on ascending, leafy stems. This species displays an unusually wide variability in leaf shape and indumentum, stem structure, and fruit size. The leaf outline may be orbicular or polygonal, and more or less divided. The middle leaf segment varies from obtriangular with three lobes to rhombic with twelve lobes. Occasionally, the leaves have a dense indumentum (only in southern Peru, Bolivia, and northern Argentina), although they are usually pilose, with scattered appressed hairs. Pedicels usually have patent to retrorse hairs; however, a few specimens from central and southern Peru have pedicels with antrorse hairs. A continuum of intermediates suggests that these forms do not deserve taxonomic recognition. Some specimens have cymules borne on the rootstock and also elongated internodes bearing a tuft of stipules from which an aggregate of cymules arises; sometimes a pair of leaves is also present at these nodes. These forms have been named *G. tucumanum* in northern Argentina, but they are also present throughout the range of *G. sessiliflorum*. Intermediate forms can be found even on the same herbarium sheet, and *G. tucumanum* is regarded as a synonym of *G. sessiliflorum*. Fruit size also shows a remarkable range of variation, between 6.8 and 19.5 mm long, but it is not correlated with leaf shape, indumentum, or stem structure.

The type of *G. malpasense* has emarginate petals that are 12 mm long, but otherwise it matches other specimens of *G. sessiliflorum*. The type of *G. weberbauerianum* is lost, but a photograph at F and the original description indicate that the name is a synonym of *G. sessiliflorum*.

**Perennial herbs**, 3.3-21(80) cm tall. **Rootstock** 7-14.3 mm in diameter, vertical, not tuberculate, turnip-shaped, without thickened roots. **Stem** prostrate (when present), usually scapiform, not rooting at nodes, stolons absent, without vegetative stems. **Basal leaves** in a persistent rosette, cauline leaves usually absent, sometimes 1(2) pairs, opposite; leaf laminae (1.1)1.6-2.6(7.7) cm long, 1.1-8.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.82-0.90], polygonal in outline, base cordate (with basal leaf segments downward), not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(6), in 1 plane, middle segment

rhombic to obtriangular, 1.1-4.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.17(0.20)], 3-9-lobed in distal half [ratio secondary sinus length/middle segment length = (0.27)0.32-0.40(0.50)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse,  $\pm$  appressed, eglandular hairs

0.2-0.5 mm long; stipules 5.1-15.3 mm long, 1.21-2.2 mm wide, lanceolate, free, papery, brownish red, glabrous or with scattered, eglandular hairs on both surfaces and on the margin. Cymes 1-flowered, solitary (rarely in aggregates of 2-4 flowers) [ratio cymule length/leaf length = 0.4-1(1.2)]; peduncles 1-94(135) mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.1-0.4

mm long; bracteoles 2.3-5.8 mm long, 0.8-1.3 mm wide, linear-lanceolate, opposite; pedicels absent or 14.5-62 mm long, usually with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.4 mm long. Flowers actinomorphic. *Sepals* (5.2)6.1-7.2(7.7) mm long, 1.8-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.6-0.9(1.4) mm long [ratio mucro length/sepal length = (0.08)0.10-0.15(0.18)], with erect-patent, eglandular hairs 0.4-0.8 mm long on the abaxial surface, glabrous adaxially. *Petals* (9.5)11.5-15.7 mm long, 3.2-9.4 mm wide, erect-patent, rounded, without claw, white, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.3-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.3-5.9 mm long, lanceolate, white to green, with eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers 0.9-1.4 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3.7-6.5 mm long, white to green. *Fruit* 16.2-20.4 mm long, erect, discharge of seed-ejection type; mericarps 3.2-4.1 mm long, 1.2-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth (sometimes with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.6 mm long; rostrum 9.57-13.6 mm long, with a narrowed apex 0.7-1.5 mm long, not twisted, with erect-patent, eglandular hairs 0.2-0.5 mm long; stigmatic remnants (1.7)2-2.3(2.5) mm long, with 5 glabrous lobes. *Seeds* 2.3-2.8 mm long, 1.2-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 317, 318.

*Pollen*. *Geranium*-type (Aedo & al. 2005a: 6).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from November to February.

*Distribution*. This species is endemic to northwestern Argentina (Fig. 319).

*Habitat*. Puna grassland; 1800-2600 m.

**Discussion.** *Geranium parodii* is endemic to the Sierra de Achala of Argentina. It has been described once as a variety of *G. sessiliflorum* and twice of *G. magellanicum*; however, *G. parodii* differs sufficiently to merit specific rank. In *G. parodii* the petals are (9.5)11.5-15.7 mm long, and hairy abaxially and on the margin; *G. sessiliflorum* and *G. magellanicum* have shorter petals (in the case of *G. sessiliflorum* with some overlap) with only a few cilia on the basal margin. Additionally, *G. parodii* has hairy nectaries and a fruit rostrum with a narrowed apex 0.7-1.5 mm long, whereas *G. sessiliflorum* and *G. magellanicum* have glabrous nectaries, and the fruit rostrum lacks a narrowed apex. The sepals of *G. parodii* usually have a mucro longer than that found in *G. sessiliflorum* and *G. magellanicum*, and have a more homogeneous indumentum (without longer hairs on the margin). The fruits and rostrum, pedicels, and gynoecium of *G. parodii* are longer than those of *G. sessiliflorum*. *Geranium parodii* shows some variation in plant size and cymule structure. Small specimens have short 1-flowered cymules without a pedicel and show a strong resemblance to *G. sessiliflorum* in habit (some are cushion-like). They are usually found in open habitats among short grasses. In contrast, more robust plants of *G. parodii* are

found in areas with tall grasses. These plants have, in addition to cymules borne on the rootstock, elongated internodes bearing a tuft of stipules from which arises an aggregate of cymules. Sometimes a pair of leaves is also present at these nodes. Such cymules can be 1-flowered or aggregates of 2-4 flowers. A continuum of intermediate individuals suggests that these forms do not deserve taxonomic recognition. Petal size, indumentum of petals and nectaries, and rostrum shape are constant and strongly support recognition of *G. parodii* at the rank of species. Knuth (1912) based *G. magellanicum* var. *pumilum* on heterogeneous gatherings, e.g., Hieronymus 449 is *G. core-core* and Lorentz & Hieronymus 585 is *G. leucanthum*. Aedo & al. (2005a) designated the G duplicate of Hieronymus s.n., a specimen of *G. parodii*, as lectotype.

**The Carolinianum Group**—This group is characterized by its erect or ascending habit, its annual life span, and its usually 2-flowered cymules arranged in dichasial inflorescence. The leaves are palmatifid, alternate in middle of the stem and distally opposite, the sepals are accrescent, and the petals are of small size and without claw.

*Geranium carolinianum* f. *albiflorum* B. Boivin, Naturaliste Canad. 93: 1060. 1967. TYPE LOCALITY: "W.J. Dore 20292, Hasting Co., E. of Belleville, Point Anne, 15 June 1963 (DAO), type". TYPE: Canada. Ontario, Hastings Co., Point Anne, 44°10'N, 77°23'W, 15 June 1963, W.G. Dore 20292 (holotype, DAO!).

**Annual herbs**, 10-65(70) cm tall. **Stem** erect, leafy, with patent to retrorse, eglandular hairs 0.2-1.1 mm long and scattered, patent, glandular hairs 0.2-0.7 mm long. **Basal leaves** in a ± deciduous rosette, cauline leaves alternate and upper opposite; leaf laminae (2.1)2.3-3(6.5) cm long, 2.3-8.5 cm wide, not peltate, palmatifid

[ratio main-sinus length/middle segment length = (0.81)0.84-0.89(0.91)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, (2)2.1-3.3(3.4) mm wide at the base [ratio segment width at the base/middle segment length = 0.11-0.13(0.17)], (5)8-13-lobed in distal half [ratio secondary sinus length/middle segment length = 0.30-0.32(0.38)]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with usually patent, eglandular hairs 0.2-1.1 mm long and scattered, glandular hairs 0.2-0.4 mm long; stipules 4-10 mm long, 0.7-2 mm wide, lanceolate to subulate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2(3)-flowered, in dense aggregates at the top of each branch or solitary in the forks [ratio cymule length/leaf length = (0.5)1-1.3(1.4)]; peduncles 3-25(60) mm long, with patent (sometimes  $\pm$  retrorse), eglandular 0.2-0.9 mm long and, sometimes, patent, glandular hairs 0.2-0.5 mm long; bracteoles 2.7-4.4 mm long, 0.4-1 mm wide, lanceolate, whorled; pedicels (3)4-6(13) mm long, with patent, sometimes retrorse, not appressed, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.3-0.6 mm long. Flowers actinomorphic. *Sepals* (5)5.1-5.9(6.3) mm long, 2.5-4 mm wide, broadly lanceolate, smooth, accrescent, nerves 3(5), mucro (0.9)1-1.4(2) mm long [ratio mucro length/sepal length = 0.19-0.24], with antrorse to patent, eglandular hairs 0.1-1.4 mm long and patent, glandular hairs 0.2-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* 4.5-6 mm long, 1.3-2.1 mm wide, erect-patent, rounded or slightly emarginate, without claw, white to pale purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; fila-

ments 2.5-3(4) mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.3 mm long; anthers 0.4-0.6 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.6-5.4 mm long, pink. *Fruit* 15-19(25) mm long, erect, discharge of seed-ejection type; mericarps 2.8-4.5 mm long, 1.4-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black, with patent to antrorse, eglandular hairs 0.5-1.9 mm long and, sometimes, patent glandular hairs 0.4-1 mm long; rostrum 11.2-19 mm long, with a narrowed apex 0.5-2 mm long, not twisted, with patent, eglandular hairs 0.1-0.8 mm long and patent, glandular hairs 0.3-0.6 mm long; stigmatic remnants 0.7-1.4 mm long, with 5 hairy lobes. *Seeds* 1.7-2.3 mm long, 1-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 320.

*Pollen*. *Geranium*-type (Aedo 2000: 46; Park & Kim 1997: 312).

*Chromosome number*.  $2n = 46-48, 52$ .

*Phenology*. Collected in flower from February to December.

*Distribution*. This species ranges through southern Canada, U.S.A. and north Mexico and it is introduced in Bahamas, Dominican Republic, Jamaica, southern South America, Europe (Czech Republic, Finland, Norway and Portugal), China, Japan and Réunion (Fig. 321).

*Habitat*. Disturbed areas, roadsides, open fields, grassy slopes, prairies, and open deciduous and evergreen forests; 0-2900 m.

*Representative specimens examined*. **Argentina**. BUENOS AIRES: Avellaneda, Darseña de Inflamables, Dock Sud, 34°39'S, 58°23'W, 24 Nov. 1945, *Krapovickas* 2688 (GH, MO, NY). **Discussion.** *Geranium carolinianum* is an annual easily identified by its dense aggregates of cymules at the apex of each branch, and its accrescent and very wide sepals. *Geranium carolinianum* shares with *G. bicknellii* and *G. texanum*, the two other native annuals in North America, an accrescent calyx and blackish mericarps; however, *G. bicknellii* has a distinctive rostrum with a long narrowed apex, and *G. texanum* bears an indumentum of appressed eglandular hairs not present in *G. carolinianum*. *Geranium columbinum* is an Old-World native annual species that could be mistaken for *G. carolinianum* because of its accrescent and wide sepals, but, unlike *G. columbinum*, *G. carolinianum* has long petals, usually opposite leaves (in *G. carolinianum* the cauline leaves at the middle of the stem are alternate), solitary cymules, appressed eglandular hairs on the stem and inflorescence, brownish mericarps with short hairs, and fruits with the rostrum terminating in a well-developed narrowed apex.

A number of minor morphological variants of *G. carolinianum* have been recognized in the literature, of which

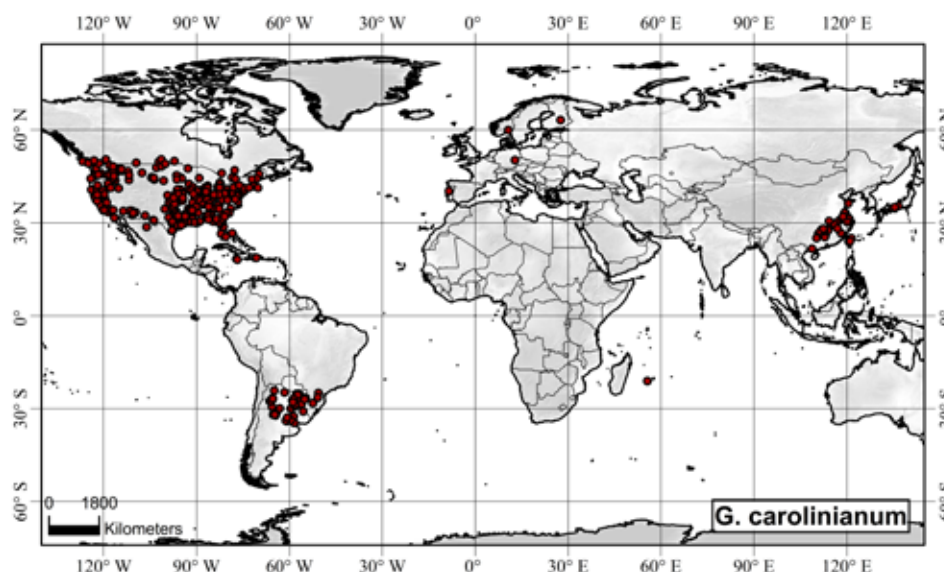

Fig. 321. Distribution of *Geranium carolinianum*.

the most notable is *G. sphaerospermum*. According to Fernald (1935), *G. sphaerospermum* is characterized by its 5-nerved eglandular sepals and its subspherical seeds; yet, these characteristics are within the variation found in *G. carolinianum*. In some individuals the number of nerves per sepal varies between three and five in the same inflorescence; glandular hairs can be restricted to the pedicels or widespread throughout inflorescence and stem; and the seeds can be subspherical to elongate with many intermediate forms. Because all these characters vary considerably but independently, *G. sphaerospermum* was not accorded taxonomic recognition (Aedo 2012). A similar view was presented by McGregor (1986: 581). According to Moore (1943: 102-103), some collections from San Luis Potosí, Mexico, which Watson (1882: 334) referred to *G. carolinianum*, are perennial and may represent *G. tenue*. Examination of these specimens showed that they belong to *G. seemannii* subsp. *seemannii*. *Geranium carolinianum* is known from only two Mexican localities, and additional field work likely would yield more records. Whether *G. carolinianum* is native in the Caribbean is difficult to ascertain, but it is certainly introduced in temperate South

America, eastern Asia, and Europe. Shirk & al. (2014) studied the patterns of genetic diversity of *G. carolinianum* using allozymes and microsatellites to discern its colonization history in China. Their results suggest a reduced diversity in China and provide evidence for multiple introductions near Nanjing with subsequent range expansion to the west and south. Sharma & al. (1988) recorded *G. carolinianum* from the Punjab, in northwestern India (Sharma 9689, 14309, 12497, PUN), in garden beds. Unfortunately, it has not been possible to study the voucher of such record.

patent, glandular hairs 0.2-0.5 mm long on the abaxial surface (mainly on the nerves), glabrous adaxially. *Petals* 3.3-6.9 mm long, 1.1-3 mm wide, erect-patent, emarginate (notch ca. 0.5 mm deep), without claw, pale purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3-4 mm long, lanceolate, white, glabrous except for a some cilia 0.1-0.2 mm long on the proximal half; anthers 0.5-0.6 mm long, dark blue. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 3-5 mm long, purple. *Fruit* 18-25 mm long, erect, discharge of seed-ejection type; mericarps 2.8-3.5 mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, black, with antrorse, eglandular hairs 0.4-1.2 mm long and sometimes, patent, glandular hairs 0.2-0.5 mm long; rostrum 13-21 mm long, with a narrowed apex 2-5.6 mm long, not twisted, with patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.2-0.6 mm long; stigmatic remnants 1-1.5 mm long, with 5 hairy lobes. *Seeds* 1.6-2.4 mm long, 0.9-1.3 mm wide, reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 322, 323.

*Pollen*. *Geranium*-type (Aedo 2000: 46).

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges through Canada and U.S.A. and it is introduced in China, Colombia and Venezuela (Fig. 324).

*Habitat*. Disturbed areas, meadows, clearings in evergreen and deciduous forests; 0-2700 m.

*Representative specimens examined*.

**Discussion.** *Geranium bicknellii* shares with *G. carolinianum* and *G. texanum* an accrescent calyx and blackish mericarps; however, it is easily distinguished by the long narrowed apex of the fruit rostrum. Although the calyx of *G. bicknellii* is accrescent, it is narrower than in *G. carolinianum* and *G. texanum*. *Geranium bicknellii* and *G. carolinianum* have long eglandular hairs towards the apex of the mericarps, while in *G. texanum* the mericarp indumentum is homogeneous and consists of shorter hairs. The blackish mericarps of *G. bicknellii* (and allies) are similar to those of *G. bohemicum*, which may be a pyrophytic adaptation. Milberg (1994) suggested that *G. bohemicum* can emerge from a bank of long-lived seeds after forest fires. Abrams & Dickmann (1984) indicated a heat requirement for germination of buried seed of *G. bicknellii*. The different morphologies of the fruits (there is no callus in *G. bohemicum*) suggests that these traits arose independently. Knuth (1912: 54) recorded *G. bicknellii* from Mexico, but Moore (1943: 99) identified these collections as *G. kerberi* R. Knuth. Here these collections are assigned to *G. seemannii* subsp. *seemannii*. The presence of *G. bick-*

*nellii* in Venezuela probably is owing to an old introduction. A recent collection in China would indicate that this weed is expanding.

**Annual herbs**, 10-48 cm tall. **Stem** erect or ascending, leafy, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long. **Basal leaves** in a ± deciduous rosette, cauline leaves alternate in middle of shoot and upper opposite; leaf laminae 1.7-4.7 cm long, 2.2-6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.90], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 2.1-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.22], (3)5-9-lobed in distal half [ratio secondary sinus length/middle segment length = 0.25-0.35]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; stipules 2.6-7 mm long, 1.1-2.9 mm wide, lanceolate to subulate, free, papery, brown, with eglandular hairs on ab-

axial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme, with monochasial branches; cymules 2-flowered, usually solitary (sometimes in scattered aggregates at the top of each branch) [ratio cymule length/leaf length = 0.4-2.2]; peduncles 10-18(50) mm long, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long; bracteoles 2.4-3.3 mm long, 0.8-0.9 mm wide, lanceolate, whorled; pedicels absent or 4-14.8 mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long. Flowers actinomorphic. *Sepals* 3.4-4.9 mm long, 2.2-3.9 mm wide, broadly lanceolate, smooth, accrescent, nerves 3, mucro 0.6-1.4 mm long [ratio mucro length/sepal length = 0.17-0.18], with antrorse, eglandular hairs 0.1-0.6 mm long on the abaxial surface (mainly on the nerves), glabrous adaxially. *Petals* 4-5 mm long, 1.5-2 mm wide, erect-patent, rounded, without claw, white, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, external whorl lacking anthers; filaments 2.2-4 mm long, lanceolate to lanceolate with an abruptly narrowed apex, white, glabrous except for a some cilia 0.1-0.2 mm long on the proximal half; anthers 0.3-0.5 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* ca. 3 mm long, pink. *Fruit* 14-18.3 mm long, erect, discharge of seed-ejection type; mericarps 2.9-3.5 mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong,  $\pm$  black, sparsely hairy, with antrorse, eglandular hairs 0.2-0.7 mm long; rostrum 9.7-13.2 mm long, with a narrowed apex 0.5-1 mm long, not twisted, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.5-0.7 mm long, with 5 hairy lobes. *Seeds* 1.9-2.2 mm long, 1.6-1.8 mm wide,  $\pm$  reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 325, 326.

*Pollen*. *Geranium*-type (Aedo 2000: 46).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to May.

*Distribution*. This species ranges from Texas and Louisiana to Oklahoma and Alabama, in southern U.S.A. and it is introduced in California and Azores (Fig. 327).

*Habitat*. Disturbed areas, cultivated fields, clearings, and open forests; 0-700 m.

*Representative specimens examined*.

**Discussion.** *Geranium texanum* resembles *G. carolinianum*, from which it can be distinguished by the type of indumentum on the inflorescence and fruit. In *G. texanum* pedicels have retrorse, appressed, eglandular hairs, while *G. carolinianum* usually has patent, glandular and eglandular hairs. Yet, in some forms of *G. carolinianum* glandular hairs are scattered or even absent; in these forms hairs can be retrorse but are never appressed. Fruits of *G. texanum* have scattered, short hairs, whereas the fruits of *G. carolinianum* are densely covered with long hairs towards the apex. Sepals, petals, and fruits are longer in *G. carolinianum* than in *G. texanum*. Two characters suggest that *G. texanum* and *G. carolinianum* may be related: the short narrowed apex of the fruit rostrum and the short pedicels. *Geranium texanum* was described by Aedo (2012: 46) as having ten fertile stamens. However, a close inspection of the new specimens thanks to Alvin Diamond's suggestion (*in litt.*) has shown that in fact the outer whorl

lacks anthers and has very short filaments. *Geranium texanum* is easily distinguished from *G. pusillum*, the other species with only five fertile stamens, by the type of fruit, which is of the seed-ejection type in the former and of the carpel-projection type in the latter. Since *G. texanum* reaches the Mexican border in Cameron Co., Texas, it is probably present in Mexico; however, I could not find any Mexican specimens of this species. Moore (1943: 102) recorded a single sheet from Chihuahua, collected by Wright in 1852 (GH), but that is *G. carolinianum*. Collections of *G. texanum* from California and the Azores probably represent occasional introductions.

**The Caespitosum Group**—This group is characterized by its usually erect habit, its usually opposite, palmatifid leaves and its 2-flowered cymules arranged in dichasial inflorescence. The petals are of medium size, erect-patent, patent or reflexed, usually without claw, and hairy on 1/5 to 3/4 of their adaxial surface.

*Perennial herbs*, 15-70 cm tall. *Root-stock* 4-14 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.1-0.9 mm long, and often patent, glandular hairs 0.2-1.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 2.6-7.3 cm long, 3-6.4(7.5) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.72-0.92], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular (and sometimes glandular) hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular to rhombic, 2.2-7.7(10) mm wide at the base [ratio segment width at the base/middle segment length = 0.09-0.25], 3-8-lobed in distal half [ratio secondary sinus length/middle segment length = 0.12-0.26]; petioles up to 30 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.1-0.9 mm long and, often, patent, glandular hairs 0.1-1.1 mm long; stipules 3-11 mm long, 1.2-2.1 mm wide, lanceolate, free, papery, brownish red, with eglandular and, sometimes, glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or, rarely, in aggregates at the top of each branch [ratio cymule length/leaf length = 1.8-4.2]; peduncles (8)18-120(170) mm long, with patent to retrorse, eglandular hairs 0.1-0.7 mm

long and, sometimes, patent, glandular hairs 0.2-0.6 mm long; bracteoles 4-11 mm long, 0.6-1.5 mm wide, lanceolate, whorled; pedicels 18-33(49) mm long, with patent to retrorse, eglandular hairs 0.1-0.7 mm long and, sometimes, patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* 7.5-11 mm long, 2.7-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (0.5)1-1.8 mm long [ratio mucro length/sepal length = 0.11-0.25], with antrorse to patent, eglandular hairs 0.2-1 mm long and patent, glandular hairs 0.1-0.6 mm long on the abaxial surface, usually hairy on the base of the adaxial surface. *Petals* 11-15 mm long, 4-9 mm wide, patent, rounded, without claw, purple, sometimes white, hairy on the basal 1/3-1/2 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 1.4-2.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 8-11.8 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-1.5 mm long; anthers 1.9-3 mm long, pink. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 9-13 mm long, purple. *Fruit* 22-31(36) mm long, erect, discharge of seed-ejection type; mericarps 3-4.8 mm long, 2-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.8 mm long and, usually, patent, glandular hairs 0.2-0.8 mm long; rostrum 15-23 mm long, with a narrowed apex 2-3.8 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.5 mm long and, usually, patent, glandular hairs 0.5-0.6 mm long; stigmatic remnants (4)5.8-8 mm long, with 5 glabrous lobes. *Seeds* 2.5-3.5 mm long, 1.6-2.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 328.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 427).

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from March to October.

*Distribution*. This species ranges from southwestern U.S.A. to northern Mexico (Fig. 329).

*Habitat*. Disturbed areas, roadsides, rocky slopes, meadows, shrublands, evergreen and deciduous forests; 1100-3300 m.

*Representative specimens examined.*

**Discussion.** *Geranium caespitosum* is well characterized by its long, usually purplish, adaxially hairy, patent

ent petals. This species shows great variability in distribution and density of the glandular indumentum, even in the same individual. Although *G. caespitosum* has an essentially eglandular indumentum, occasionally specimens occur with glandular hairs on the stem, petioles, or the inflorescence. Furthermore, leaf shape and the portion of petal surface bearing hairs vary considerably, but independently of the presence of a glandular indumentum. According to Moore (1943: 47) *G. caespitosum* (cited as "*G. atropurpureum*"; see the following paragraph) was unnecessarily divided into several species by previous authors (Jones & Jones 1943; Knuth 1912). Moreover, Welsh & al. (1987: 313) pointed out that division of *G. caespitosum* into several taxa is possible only arbitrarily. In agreement, these forms are not accorded taxonomic recognition here. In *G. caespitosum* the glandular hairs are similar to those of *G. oreganum*, *G. richardsonii*, and *G. viscosissimum*, shorter than in *G. maculatum* and ending in a broad, usually yellow cell. *Geranium caespitosum* could be confused with *G. viscosissimum*, which has larger leaves, stem, and fruits, and shorter stigmatic remnants. *Geranium richardsonii* and *G. wislizeni* have white, erect-patent petals and dorsally hairy nectaries. In addition, *G. wislizeni* has shorter sepals and petals, although with some overlap.

Fig. 329. Distribution of *Geranium caespitosum*.

Moore (1943: 47) considered "*G. caespitosum*" as nomen dubium and preferred the name *G. atropurpureum* for this species. He recorded as *G. caespitosum* some specimens from Baja California, characterized by longer peduncles towards the base of inflorescence, which are identified here as *G. californicum*.

Osterhout (1923) analyzed the different editions of James publications in relation to the name that should be used for this species. In order to maintain nomenclatural stability I accept that the American edition of *Account of an expedition from Pittsburgh to the Rocky Mountains . . .* (James 1823a) has priority over the English edition (James 1823b). The reverse option would have the name *G. caespitosum*, unquestioned for more than 150 years, displaced by *G. intermedium* E. James.

**124. *Geranium californicum*** G.N. Jones & F.F. Jones, *Rhodora* 45: 38. 1943. *Geranium leucanthum* Small in Underw. & Britton (eds.), *N. Amer. *Geranium concinnum* G.N. Jones & F.F. Jones, *Rhodora* 45: 36. 1943. TYPE LOCALITY: "California: Kern River, Culbertson 4454". TYPE: U.S.A. California, Tulare Co., Kern River, 36°18'N, 118°24'W, 3 Aug. 1904, J.D. Culbertson 4454 (holotype, GH-00043612 image!; isotypes, MO-251026!, NY, UC!).

*Perennial herbs*, 20-70 cm tall. *Root-stock* 4-15 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-1.5 mm long and,

often, patent, glandular hairs 0.3-0.5 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminas 2.4-6 cm long, (2.8)4.1-6(8) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.92], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pi-

lose, with appressed, eglandular (and sometimes glandular) hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 3-7 mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.25], (3)7-9-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.35]; petioles

Fig. 330. *Geranium californicum*. a. Habit. b. Leaf. c. Detail of leaf, adaxial side. d. Inflorescence. e. Flower, petals removed. f. Petal. g. Staminal filament. h. Nectary. i. Fruit. j. Mericarp. (Based on: a, d-h, Hall & Chandler 224, UC; b, c, Hall 9234, UC; i, j, Ertter 6665, UC).

up to 32 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.7 mm long and, sometimes, patent, glandular hairs 0.2-0.5 mm long; stipules 2.4-12 mm long, 1.2-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or, rarely, in aggregates at the top of each branch [ratio cymule length/leaf length = 1.1-7.7]; peduncles (22)82-190(310) mm long, with patent to retrorse, eglandular hairs 0.3-1.6 mm long and patent, glandular hairs 0.2-0.6 mm long; bracteoles 2.2-11 mm long, 0.5-1.5 mm wide, lanceolate, whorled; pedicels (17)44-86 mm long, with patent to retrorse, eglandular hairs 0.2-1 mm long and patent, glandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* 6.9-11 mm long, 2.5-4.5 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (0.6)1-2 mm long [ratio mucro length/sepal length = 0.08-0.26], with antrorse to patent, eglandular hairs 0.2-1.4 mm long and, sometimes, patent, glandular hairs 0.2-0.6 mm long on the abaxial surface, usually hairy on the base of the adaxial surface. *Petals* (10)11-16.9 mm long, 6-11 mm wide, usually patent, rounded, without claw, white, sometimes purple, hairy on the basal 1/2-3/4 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 1-1.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7-11.3 mm long, lanceolate, white to pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-1.4 mm long; anthers 1.7-2.9 mm long, pink. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8.1-14 mm long, purple. *Fruit* (29)32-42 mm long, erect, discharge of seed-ejection type; mericarps 4.3-5.7 mm long, 2.1-3.5 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 2 transverse veins at the apex), without basal beak,

Fig. 331. *Geranium californicum* (Based on: a, Aedo 5450, MA).

with a basal callus, without a basal prong, brown, with  $\pm$  patent eglandular hairs 0.2-1.1 mm long and patent, glandular hairs 0.2-0.6 mm long; rostrum 19-26 mm long, with a narrowed apex (2.9)4-6.1 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and patent, glandular hairs 0.3-0.6 mm long; stigmatic remnants 4.2-8 mm long, with 5 usually hairy lobes. *Seeds* 2.5-3.3 mm long, 1.5-2 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 330, 331.

Fig. 332. Distribution of *Geranium californicum*.

*Pollen.* *Geranium*-type.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from April to October.

*Distribution.* This species ranges from central California (U.S.A.) to Baja California (Mexico) (Fig. 332).

*Habitat.* Rocky slopes, damp places, meadows, and conifer and *Quercus* L. forests; 1300-3050 m.

*Discussion.* *Geranium californicum* is similar to *G. caespitosum* but differs in its usually long peduncles at the base of the inflorescence, longer fruits, longer pedicels, and a longer narrowed apex of the rostrum. All these features show some overlap with those of the allopatric *G. caespitosum*. *Geranium californicum* can be distinguished from *G. viscosissimum* by its narrow leaves and longer stigmatic remnants. *Geranium californicum* usually bears glandular hairs on the inflorescence, although some specimens lack such hairs. The type of *G. concinnum* falls within the range of variation encompassed by my concept of *G. californicum*, which is in agreement with Taylor (1993a: 673). Jones & Jones (1943: 38) distinguished *G. concinnum* from *G. californicum* by the pubescence of pedicels and stems, and shorter stigmatic remnants (4.5-5.5 mm long); however, the type of *G. concinnum* has some stigmatic remnants 6-7 mm long. Also, the variation in pubescence in *G. californicum* includes that found in *G. concinnum*. A specimen from Clifton (Los Angeles Co.) [*Davison 610*, JEPS] has the leaves not deeply divided but matches *G. californicum* in all other characters.

**125. *Geranium dodecatheoides* P.** Alexander & Aedo. TYPE LOCALITY: "U.S.A. *Perennial herbs*, 40-100 cm tall. *Rootstock* 5.1-9.7 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.6-0.7 mm long and patent, glandular hairs 0.3-0.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae 3.7-4.4 cm long, 4.8-5.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.75], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular and glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 8.9-12.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.30-0.36], 5-7-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.23]; petioles up to 22 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.1-1 mm long and patent, glandular hairs 0.2-0.6 mm long; stipules 5-17 mm long, 1.9-4.9 mm wide, lanceolate, free, papery, brownish red, with eglandular and glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.3-2.5];

peduncles 27-46 mm long, with patent, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.5-0.6 mm long; bracteoles 5.2-8.4 mm long, 0.7-0.8 mm wide, lanceolate, whorled; pedicels 41-59 mm long, with patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.3-0.6 mm long. Flowers actinomorphic. *Sepals* 9.1-10.7 mm long, 2.9-3.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.4-1.6 mm long [ratio mucro length/sepal length = 0.14-0.18], with antrorse to patent, eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 0.5-0.8 mm long on the abaxial surface, usually hairy on the base of the adaxial surface, glabrous adaxially. *Petals* 11.9-13.8 mm long, 2.8-4.7 mm wide, reflexed, rounded, with claw 0.8-1.1 mm long, purple, hairy on the basal 1/5-1/4 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 2.1-3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 10.9-12.8 mm long, lanceolate, green, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.8 mm long; anthers 2-2.4 mm long, yellow with purplish strips. Nectaries 5, hemispheric, glabrous. *Gynoecium* 9.8-12.7 mm long, purple. *Fruit* 29.9-35.8 mm long, erect, discharge of seed-ejection type; mericarps 3.9-4.1 mm long, 1.9-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent eglandular hairs 0.5-0.9 mm long and patent, glandular hairs 0.4-0.7 mm long; rostrum 19.1-24 mm long, with a narrowed apex 6.3-7.3 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.3-0.7 mm long; stigmatic remnants 4.6-5.3 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.1 mm long, 1.5-1.9 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 333, 334.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to September.

*Distribution*. This species is endemic to central New Mexico (Fig. 335).

*Habitat*. Stream banks, talus of granitic boulders and partially burned areas in forest dominated by *Pinus* L.,

*Pseudotsuga* Carrière, and *Quercus* L.; 2300-3070 m.

*Additional specimens examined*. **USA.**

**NEW MEXICO**: Lincoln Co., Central Capitan Mountains on the Summit Trail (58) 1.3 miles (linear) east-southeast of the crest road and 4.2 miles (linear) west-northwest of Capitan Peak, 33°35'N, 105°19'W, 26 July

**Discussion.** *Geranium dodecatheoides* is similar to *G. caespitosum*, from which it differs in characters of the leaves and flowers, but most strikingly in petal orientation. The petals are reflexed in *G. dodecatheoides* and patent in *G. caespitosum*. The leaves of *G. dodecatheoides* are less deeply divided than in *G. caespitosum* (ratio main-sinus length/middle segment length: 0.65-0.75 vs. 0.72-0.92) and have the middle segment broader at the base [8.9-12.8 mm vs. 2.2-7.7(10) mm wide]. The petals are of similar length but much narrower in *G. dodecatheoides* (ratio petal width/petal length: 0.23-0.35 vs. 0.54-0.63). In *G. caespitosum* half of the adaxial petal surface is covered with hairs, whereas in *G. dodeca-*

*theoides* the hairs are restricted to the proximal quarter of the petal and are usually longer. The staminal filaments of *G. dodecatheoides* are longer than those of *G. caespitosum*, although with some overlap. The filaments of *G. dodecatheoides* are straight and remain more or less aligned with the stigmatic column during both the male and female phases of the flower. In contrast, the stamens soon arch out in *G. caespitosum*. Nectaries are glabrous in *G. dodecatheoides*, but usually have a tuft of hairs at the apex in *G. caespitosum*. Additionally, the narrowed apex of the rostrum is substantially longer in *G. dodecatheoides* than in *G. caespitosum* (6.3-7.3 mm vs. 2-3.8 mm). Both species were found together along the Three Rivers Trail, but no intermediate individuals were seen. *Geranium californicum* shares with *G. dodecatheoides* a fruit-rostrum with a long narrowed apex; however, *G. californicum* is well characterized by its longer peduncles and pedicels. *Geranium richardsonii* occurs in the same region as *G. dodecatheoides* but at higher elevations. *Geranium richardsonii* is easy to differentiate from *G. dodecatheoides* by its longer and more deeply di-

vided leaves, which have more lobes per segment, shorter sepals; larger, usually white, erect-patent petals with hairs in the basal half; shorter staminal filaments; dorsally lanate nectaries; a rostrum with a shorter narrowed apex; and shorter stigmatic remnants.

In the Balkans there are two species with reflexed petals, *G. aristatum* and *G. reflexum*, both in subg. *Erodioidea*, characterized by “*Erodium*-type” fruit dispersal. In contrast, *G. dodecatheoides* has fruits of the “seed-ejection-type”, which characteristic of subg. *Geranium* (Yeo 1984). Another group of species with reflexed petals is found in China: *G. delavayi*, *G. pogonanthum*, *G. shensianum*, *G. sinense* and *G. refractum*. They belong to subg. *Geranium*, and, compared to *G. dodecatheoides*, have longer leaves [(3.2)5-10.9 cm vs. 3.7-4.4 cm] with rhombic and many-lobed segments; connate stipules; wider petals [(3.2)4-8.4 mm vs. 2.8-4.7 mm] that sometimes bear hairs but then shorter than those of *G. dodecatheoides*; nectaries usually with a tuft of hairs at the apex (or glabrous but forming a ring around the base of the ovary); and fruits reflexed when immature and with shorter stigmatic remnants.

P. Alexander kindly informed me that since the publication of the species, Ken Heil found *G. dodecatheoides* in a second mountain range, the Capitan Mountains, ca. 50 kilometers northeast of the type locality.

*Discussion*. *Geranium lentum* is characterized by its short petals, glabrous nectaries, and stigmatic remnants that are 4-5 mm long. *Geranium wislizeni* shares short petals and sepals with *G. lentum*, but it has dorsally hairy nectaries and stigmatic remnants 1.5-3 mm long. I have not found a fully eglandular specimen of *G. lentum*, although some plants lack glandular hairs on the stem. Jones & Jones (1943: 51) recorded *G. lentum* from Texas [Chisos Mts, *Mueller 8050* (F, TEX)], more than 500 km south-east of the nearest locality in New Mexico; I assign *Mueller 8050* to *G. caespitosum*.

**127. *Geranium wislizeni* S. Watson**, Proc. Amer. Acad. Arts 21: 421. 1886, ["Wislizeni"]. TYPE LOCALITY: "Norogachi, in clefts of rocks (428) [collected by E. Palmer]; also collected by Dr. Wislizenus on the Llanos mountains, Chihuahua, and referred by Dr. Engelmann (Pl. Fendler, 27) to *G. Hernandezii*, and by myself (Proc. Amer. Acad. 17. 334) to *G. Mexicanum*". TYPE: Mexico. Chihuahua, Norogachi, 29°30'N, 107°45'W, Nov. 1885, *E. Palmer 428* (lectotype, designated by Moore 1943: 33, GH-00043662!; isolectotypes, K!, LE-00002584!, NY-00370259!, US-00100929 image!).

*Perennial herbs*, 20-60 cm tall. *Rootstock* 3-9 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, appressed, eglandular hairs 0.3-1.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite;

leaf laminae 2.9-6.6(8) cm long, 3.6-7.1(9.8) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.74-0.93], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular (and sometimes glandular) hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 4.4-10.5(14.3) mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.35], 5-15-lobed in distal half [ratio secondary sinus length/middle segment length = 0.11-0.22]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.5 mm long; stipules 3.4-18 mm long, 1-2.4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.3-7.9]; peduncles 19-57(119) mm long, with patent to retrorse, eglandular hairs 0.2-1.2 mm long and, sometimes, patent, glandular hairs 0.2-0.7 mm long; bracteoles 1.7-7.8 mm long, 0.5-1.2 mm wide, lanceolate, whorled; pedicels 4-31 mm long, with patent to retrorse, eglandular hairs 0.2-1.2 mm long and, sometimes, patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* 4.5-5.8(6.8) mm long, 1.7-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-2.3 mm long [ratio mucro length/sepal length = 0.14-0.42], with antrorse to patent, eglandular hairs 0.3-1.1 mm long and, occasionally, patent, glandular hairs 0.2-0.6 mm long on the abaxial surface, glabrous adaxially. *Petals* 6-10.3(13.1) mm long, 2.9-6.5 mm wide, erect-patent, rounded, without claw, white, hairy on the basal 1/3-1/2 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.6-1.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4-7.6 mm long, lan-

ceolate, white to pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.8 mm long; anthers 0.6-1.4 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs covering all of its surface. *Gynoecium* 3.1-7.7 mm long, yellow. *Fruit* 17-25 mm long, erect, discharge of seed-ejection type; mericarps 2.4-3.7 mm long, 1.4-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-0.7 mm long and, sometimes, patent, glandular hairs 0.2-0.4 mm long; rostrum 10.4-17.6 mm long, with a narrowed apex 1.6-2.8(3) mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long and, usually, glandular hairs 0.4-0.7 mm long; stigmatic remnants 1.5-3.3 mm long, with 5 glabrous lobes. *Seeds* 2-2.5 mm long, 1-1.5 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 338.

*Pollen.* *Geranium*-type (Aedo 2001a: 17).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from April to November.

*Distribution.* This species ranges from southwestern U.S.A. to western Mexico (Fig. 339).

*Habitat.* Base of cliffs and on rocky slopes, in conifer and *Quercus* L. forests; 200-3300 m.

*Representative specimens examined.*

**Discussion.** *Geranium wislizeni* is well characterized by its short, white, erect-patent petals covered adaxially by long hairs. *Geranium caespitosum* is partially sympatric, but it has longer, usually purplish and patent petals, and nectaries with a tuft of hairs at the apex. The nectaries of *G. wislizeni* resemble those of *G. rich-*

*ardsonii*, because they are covered dorsally with hairs; this vesture is composed of long hairs in *G. wislizeni* and is short-lanate in *G. richardsonii*. Both species also share with *G. wislizeni* white, erect, patent petals. Where their ranges overlap, the differences between *G. richardsonii* and *G. wislizeni* are sometimes difficult to ascertain; yet, both species are well characterized. *Geranium richardsonii* is usually a robust plant with longer petals, sepals, and fruits, and has glandular hairs on the stem. The variation in glandular indumentum *G. wislizeni* is similar to that found in *G. caespitosum*; therefore lack of glandular hairs cannot be used to separate *G. wislizeni* from *G. lentum*, as proposed by Jones & Jones (1943); see the discussion of *G. lentum*. *Geranium albidum* was recognized by Moore (1943: 28) as a separate species; however, it seems to be only a local form of *G. wislizeni* with deeply divided leaves, narrowed leaf segments, and without any glandular hairs. Other features mentioned by Moore (1943: 28), such as the longer narrowed apex of the rostrum, color of staminal filaments, and petal veins, are also included within the variability of *G. wislizeni*. A set of specimens (Rose 222; F, MEXU, NMC, NY, P, UC) obtained at the type locality of *G. albidum* belongs unequivocally to *G. wislizeni*.

*Perennial herbs*, 15-90 cm tall. *Root-stock* 5-12 mm in diameter, horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-0.7 mm long and, sometimes, patent, glandular hairs 0.3-0.9 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminas (3.9)4.5-10.5 cm long, (4.4)6-12.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.81-0.90], polygonal in

outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 5-13.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.27], 6-11(16)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.17-0.30]; petioles up to 44 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.2-0.9 mm long and, sometimes, patent, glandular hairs 0.3-0.9 mm long; stipules 4.8-11 mm long, 1.3-4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.5-2.6]; peduncles 25-94(102) mm long, with patent to retrorse, eglandular hairs 0.1-0.8 mm long and, sometimes, patent, glandular hairs 0.2-0.9 mm long; bracteoles 3.3-10 mm long, 0.7-1.7 mm wide, lanceolate, whorled; pedicels 12-30 mm long, with patent to retrorse, eglandular hairs 0.1-0.4 mm long and, usually, patent, glandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* (6.5)7-8.2 mm long, 2.1-4.4 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1-3 mm long [ratio mucro length/sepal length = 0.18-0.38], with antrorse, appressed, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.3-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.2)14-20 mm long, 5.8-15 mm wide, erect-patent, rounded, without claw, usually white, hairy on the basal 1/3-1/2 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.9-1.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.3-9 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-1 mm long; anthers 1.5-1.7 mm long, lilac or yellow. *Nectaries* 5, hemispheric, dorsally lanate.

*Gynoecium* 5.1-10.5 mm long, green to pink. *Fruit* 19-26(32) mm long, erect, discharge of seed-ejection type; mericarps 3.5-4.9 mm long, 2-3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long and patent, glandular hairs 0.3-0.9 mm long; rostrum 13-17(21) mm long, with a narrowed apex 1-2(3.6) mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and glandular hairs 0.3-0.9 mm long; stigmatic remnants 3-4.2 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.3 mm long, 1.5-1.9 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 340, 341.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 455).

*Chromosome number*.  $2n = 52, 56$ .

*Phenology*. Collected in flower from March to September.

*Distribution*. This species ranges through western Canada and western U.S.A. (Fig. 342).

*Habitat*. Forested roadsides, moist meadows, alpine slopes, open shrublands, evergreen and deciduous forests; 650-4000 m.

#### *Representative specimens examined.*

OREGON: Harney Co., 1 mi S of Calamity Guard Station, 43°55'N, 118°49'W, 26 June 1953, *McCutcheon 620* (WVA); Jackson Co., High Cascades E of Medford, 42°19'N, 122°52'W, June, *Heckner s.n.* (WTU); Klamath Co., Crater National Forest, Cascade Mts., Cherry Creek, 43°34'N, 122°2'W, Aug., *Rose 1148* (MO); Sheep Mountain, near Fire Warden's Cabin, 34 mi N of Natal, 49°51'N, 114°48'W, 7 July 1941, *Weber 2342* (MO, WTU). SOUTH DAKOTA: Custer Co., Custer, 46°48'N, 100°47'W, 30 July 1942, *Degener 16284* (NY); Lawrence Co., Spearfish Canyon, 44°28'N, 103°50'W, 31 July 1938, *Hapeman s.n.* (MO); Pennington Co., Rockerville, Black Hills, 43°57'N, 103°21'W, 1906, *White s.n.* (MO). UTAH: Daggett Co., 4 mi N of Mt. Home, 40°56'N, 109°11'W, 13 June 1934, *Harrison & Larsen 7590* (MO); Iron Co., Cedar Breaks, above the Breaks, 37°38'N, 112°50'W, 19 July 1929, *Mathias 697* (MO); Piute Co., 2 mi NW junction T29S, R3W, 38°15'N, 112°7'W, 28 July 1976, *Welsh & al. 14110* (MO); Uintah Co., Uinta Mts., E of Mirror Lake, 40°42'N, 110°53'W, 19 Aug. 1955, *Holmgren & Anderson 10964* (MO); Weber Co., Ogden, 41°13'N, 111°58'W, 2 Aug. 1887, *Tracy 612* (MO). WYOMING: Albany Co., 3.6 mi W of Centennial, 41°15'N, 106°12'W, 11 Aug. 1984, *Miller & Lowry II 1939* (MO); Carbon Co., Medicine Bow Range, Arlington, 41°59'N, 106°40'W, 15 July 1988, *Nieto Feliner & Lansac 2090* (MA); Sublette Co., 25 mi W Big Piney, N side of Middle Piney Lake, 42°35'N, 110°34'W, 31 Aug. 1947, *Meyer & Meyer 2404* (MO); Teton Co., Firehole River, 3 mi SW of Loop Rd. Yellowstone National Park, 44°38'N, 110°51'W, 27 June 1960, *Venrick 396* (MO).

**Discussion.** *Geranium richardsonii* is readily recognized by its white, long, erect-patent, adaxially hairy petals and its hairy nectaries. In some specimens from Utah, Colorado, and California nectary indumentum is sparse and difficult to see, but the short intermingled hairs cover the entire abaxial side. The presence of glandular hairs varies considerably (as in *G. caespitosum*). Some specimens have abundant glandular hairs on the stem base, petioles, and inflorescence, while others have only few glandular hairs on the pedicels. Surprisingly, this variability has not led to the description of a large number of segregate taxa, as in *G. caespitosum*. *Geranium richardsonii* shares a part of its range with *G. caespitosum* and *G. californicum*, and sometimes it is difficult to differentiate between these species; however, they have usually patent petals and nectaries with a tuft of hairs at the apex. Additionally, *G. californicum* has notably long peduncles. *Geranium richardsonii* closely resembles *G. wislizeni*, a southern species also with hairy nectaries and white petals; see the discussion under the latter.

An account of some aspects of the life history of *G. richardsonii* is provided by Green (1978).

**129. *Geranium viscosissimum*** Fisch. & C.A. Mey. in C.A. Mey., Index Sem. Hort. Petrop. 11, Suppl.: 18. 1846, [imprimatur, Dec. 1846, probably 1847]. **Perennial herbs**, (30)50-90 cm tall. **Rootstock** 6-22 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-1.9 mm long and, usually, patent, glandular hairs 0.1-0.8 mm long. **Basal leaves** in a persistent rosette, cauline leaves opposite; leaf laminas 6.8-15 cm long, (7.1)10-16 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.92], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular (and sometimes glandular) hairs on both surfaces; segments 5-7, in 1 plane, middle segment rhombic, 7-15 mm wide at the base [ratio segment width at the base/middle seg-

ment length = 0.14-0.20], 9-17-lobed in distal half [ratio secondary sinus length/middle segment length = 0.14-0.28(0.40)]; petioles up to 35 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.8 mm long and, sometimes, patent glandular hairs 0.3-0.9 mm long; stipules 8.2-15 mm long, 2-5 mm wide,

lanceolate, free, papery, brownish red, with eglandular and, sometimes, glandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (0.8)1.2-5.4]; peduncles 10-80(130) mm long, with patent to retrorse, eglandular hairs 0.2-1.9 mm

long and, sometimes, patent, glandular hairs 0.3-0.9 mm long; bracteoles 5-10 mm long, 1-2 mm wide, lanceolate, whorled; pedicels absent or 6-57 mm long, with patent to retrorse, eglandular hairs 0.1-1.9 mm long and, usually, patent, glandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* 7.7-11 mm long, 3-4.7 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1-2.7 mm long [ratio mucro length/sepal length = 0.20-0.29], with antrorse, appressed, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.3-1.1 mm long on the abaxial surface, usually hairy on the base of the adaxial surface. *Petals* (15.2)17-20 mm long, 9-15 mm wide, erect-patent, rounded, without claw, purple, hairy on the basal 1/3-1/2 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 1-1.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7.7-12.2 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-1.8 mm long; anthers 2-2.5 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 7.5-13 mm long, purple. *Fruit* 31-41 mm long, erect, discharge of seed-ejection type; mericarps 4.2-5.5 mm long, 2-3 mm wide, without a strand of fibers, not compressed at the apex, smooth

(with 2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-0.5 mm long and glandular hairs 0.3-0.9 mm long; rostrum 20-29 mm long, with a narrowed apex 3-5.2 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and glandular hairs 0.5-0.9 mm long; stigmatic remnants 3-6(6.8) mm long, with 5 glabrous lobes. *Seeds* 3.1-4 mm long, 1.8-2.5 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 343.

*Pollen*. *Geranium*-type.

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from February to September.

*Distribution*. This species ranges through southwestern Canada and northwestern U.S.A. (Fig. 344).

*Habitat*. Roadsides, sandy banks, wet meadows, grassy slopes, evergreen and deciduous forests; 300-3200 m.

*Representative specimens examined*. **Canada**. *Discussion*. *Geranium viscosissimum* is sometimes difficult to differentiate from the similar *G. caespitosum*, with which it overlaps in Utah, Colorado, and Wyoming. *Geranium viscosissimum* is of robust stature with

very wide basal leaves and short stigmatic remnants, although with some overlap with *G. caespitosum*. The presence of glandular hairs also varies in *G. viscosissimum*. Forms with eglandular stems, and more rarely with eglandular peduncles and pedicels, appear at some localities of its range; however, all possible transitions from eglandular to glandular forms occur, which demonstrate that eglandular specimens do not deserve taxonomic recognition; *G. strigosum* was erected to include such eglandular specimens. Leaf shape and the portion of petal surface bearing hairs vary considerably but independently of the presence of a glandular indumentum; *G. attenuilobum* was segregated to include forms with petals bearing hairs on more than one-third of the surface.

An account of some aspects of the life history of *G. viscosissimum* [as *G. nervosum*] is provided by Green (1978). Spomer (1999) found that some sticky plants as *G. viscosissimum* were protocarnivorous, because they "were capable of digesting arthropods or other organic items trapped on the surface and absorbing the nitrogen".

**130. *Geranium latum*** Small in Underw. & Britton (eds.), N. Amer. Fl. 25(1): 18. 1907. TYPE LOCALITY: "Type collected on Popocatepetl, Mexico, August 7 and 8, 1901, J. N. Rose & R. Hay 6065". *Perennial herbs*, 25-112 cm tall. *Rootstock* 2-6.4 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate to ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.5-1.4 mm long. *Basal leaves* few, not long persistent, cauline leaves alternate (usually 1(2)) in middle of shoot and upper opposite; leaf laminae 4.2-9.9 cm long, 4.8-10.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.74-0.89], polygonal (medium and upper hastate) in outline, base cordate (medium and upper  $\pm$  truncate), not coriaceous, with nerves not projected, pilose on both surfaces, with  $\pm$  appressed, eglandular hairs; segments 3-5, in 1 plane, middle segment rhombic, 7-14.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.17-0.37], 7-12(15)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.08-0.19]; petioles up to 22 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.5-1.3 mm long; stipules 3.8-15 mm long, 1-3.2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.5-8]; peduncles (36)44-93(114) mm long, with patent to retrorse, eglandular hairs 0.3-1 mm long and patent, glandular hairs 0.2-0.5 mm long; bracteoles 4.2-8.3 mm long, 0.3-1.1 mm wide, lanceolate, whorled; pedicels (16)19-31(50) mm long, with patent to retrorse, eglandular hairs 0.2-1 mm long and patent, glandular hairs 0.2-0.8 mm long. Flowers actinomorphic. *Sepals* (4.5)5.5-7.7(8.7) mm long, 1.7-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.8-

3(3) mm long [ratio mucro length/sepal length = 0.13-0.46], with antrorse to patent, eglandular hairs 0.1-1.2 mm long and patent, glandular hairs 0.4-0.8 mm on the abaxial surface, glabrous adaxially. *Petals* (8.5)10-13.1(17.2) mm long, 4.7-10.5 mm wide, erect-patent, rounded or slightly emarginate (notch 0.2-0.6 mm deep), without claw, white to pink, hairy on the basal 1/2-3/4 of their adaxial surface, ciliate on the basal margin, with hairs 1.2-2.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.4-7.8 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs (0.7)1.3-1.6(2) mm long; anthers 1.2-1.4 mm long, black. Nectaries 5, hemispheric, with a tuft of hairs covering all of its surface. *Gynoecium* 4.5-8.7 mm long, purple. *Fruit* 23.2-32.4 mm long, erect, discharge of seed-ejection type; mericarps 3.1-4.4 mm long, 1.4-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.8 mm long and, rarely, patent, glandular hairs 0.4-0.5 mm long; rostrum 15.5-21 mm long, with a narrowed apex 1.7-3.5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.5 mm long and, rarely, patent, glandular 0.6-0.8 mm long; stigmatic remnants 2.8-4.3 mm long, with 5 glabrous lobes. *Seeds* 2.1-2.5 mm long, 1.5-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 345.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from May to November.

*Distribution*. This species ranges through central Mexico (Fig. 346).

*Habitat*. Wet slopes, moist ravines, and *Abies* Mill., *Cupressus* L., *Pinus* L., and *Quercus* L. forests; 1700-3350 m.

*Discussion.* *Geranium latum*, an endemic of the Meseta Central of Mexico, is well characterized by its adaxially densely hairy petals, staminal filaments with long hairs, nectaries with a tuft of hairs covering the

entire surface, dichasially branched, glandular-pubescent inflorescence, and alternate basal cauline leaves. The incomplete specimens seen do not permit a full reconstruction of the basal parts of the plant. *Gerani-*

*um latum* seems to have a moderately robust rootstock (only a fragment available on two sheets) giving rise to a  $\pm$  horizontal, thin, lignified branch 6-11 cm long. These branches may remain underground and are not covered by stipule remains. Middle and distal leaves are opposite, but in most specimens one (rarely two) alternate cauline leaf appears between the base and the first branch point. The basal leaves are pentagonal in outline, with five segments, and they form a  $\pm$  persistent rosette, whereas the cauline leaves are hastate, with a  $\pm$  truncate base and three segments. The inflorescence of well-developed specimens is dichasial and terminal, sometimes with single cymules at lower nodes. In small specimens the inflorescence may be reduced to one or two terminal cymules. Specimens of *G. latum* are sometimes misidentified as *G. mexicanum*, which differs in that the petals bear hairs only at the base of the adaxial surface, the staminal filaments have short hairs, and the nectaries are glabrous. *Geranium latum* is also partially sympatric with *G. deltoideum*. The species share the dense adaxial petal vestiture and nectaries with a tuft of hairs covering the entire surface; however, *G. deltoideum* has short hairs on the staminal filaments and a monochasially branched inflorescence.

Fig. 348. Distribution of *Geranium tenue*.

1.5 mm long [ratio mucro length/sepal length = 0.10-0.20], with  $\pm$  patent, eglandular hairs 0.5-1.1 mm long and sometimes, patent, glandular hairs 0.2-0.5 mm long on the abaxial surface, sparsely hairy adaxially. *Petals* 10.8-11.3 mm long, 4-5 mm wide, erect-patent, rounded, without claw, white, hairy on the basal 1/2-3/4 of their adaxial surface, ciliate on the basal margin, with hairs 1-1.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.7-7.5 mm long, lanceolate, unknown color, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.5-1.2 mm long; anthers unknown. Nectaries 5, hemispheric, with a tuft of hairs covering all of its surface. *Gynoecium* 6.5-9 mm long, unknown color. *Fruit* 23.6-29.1 mm long, erect, discharge of seed-ejection type; mericarps 3.4-3.6 mm long, 1.6-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.4-0.5 mm long; rostrum 17.3-20.4 mm long, with a narrowed apex 2.7-3.4 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.7 mm long and patent, glandular hairs 0.4-0.6 mm long; stigmatic remnants 3.1-3.3 mm long, with 5 glabrous lobes. *Seeds* 2.3-2.4 mm long, 1.5-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 347.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Unknown.

*Distribution*. This species ranges through San Luis Potosí, in central Mexico (Fig. 348).

*Habitat*. Unknown; 1800-2300 m.

*Additional specimens examined*. **Mexico**. SAN LUIS POTOSÍ: ex convalli San Luis Potosí, in montibus San Rafael, 22°11'N, 100°40'W, 1877, *Schaffner 187* (GH, MEXU).

*Discussion*. *Geranium tenue* resembles *G. latum* in that both have petals with hairs over most of the adaxi-

al surface and nectaries with a tuft of hairs covering the entire surface. Both species also have quite similar basal parts; however, the scarcity of available material for *G. tenue* suggests that confirmation of this trait is needed. *Geranium tenue* has shorter and more deeply divided leaves than *G. latum*, and the middle segment of its leaves has a narrowed base and less lobed apex. In *G. tenue* all leaves are opposite, whereas in *G. latum* the basal leaf is usually alternate. The indumentum of *G. tenue* consists of retrorse, appressed hairs on the stem and inflorescence, and rarely some glandular hairs on pedicels, but in *G. latum* glandular hairs are always present in the inflorescence. The eglandular hairs of the staminal filaments as well as the sepal mucro are shorter in *G. tenue* than in *G. latum*. Because *G. tenue* is poorly collected, such features as petal length, anther morphology, and fruit and seed characters should be reviewed when additional material becomes available. *Geranium wislizeni* is another species similar to *G. tenue*. The rootstock of *G. tenue*, although not well known, seems to be  $\pm$  horizontal, branched towards the apex, and is much thinner than that of *G. wislizeni*, which has a robust, vertical rootstock. Furthermore, *G. tenue* has shorter leaves that are less lobed per segment and a stem indumentum of retrorse, appressed short eglandular hairs. The ranges of the species are separated by a gap of about 350 km.

The holotype of *G. tenue* is *Schaffner 458* (NY). This sheet bears a printed label (locality, collector, and date) and a handwritten one (identification and collection number), which show two collection numbers: 458 and 186, apparently written by different hands. In MEXU there is a specimen with a similar label, but it has only the number 186 (written by the same hand as that of the NY sheet). In F and GH there are two specimens numbered 186, with a more precise locality ("in montibus San Miguelito") and dated 1876. Specimens at F, GH, and MEXU could be duplicates of the origi-

nal collection (and thus isotypes) but were labeled at different times and with some minor differences. *Schaffner 190* (GH) and *Parry & Palmer 101* (GH, US) were determined by Watson (1882: 334) as *G. carolinianum*. Moore (1943: 44) discussed this matter under *G. tenue*; he concluded that the specimens are similar to *G. carolinianum* but perennial, and that they may be related to *G. tenue*. I assigned these specimens to *G. seemannii* subsp. *seemannii*.

---

**132. *Geranium potosinum*** H.E. Moore, Contr. Gray Herb. 146: 41, pl. 4 fig. 3. 1943. TYPE LOCALITY: "MEXICO: Nuevo Leon: abundant in the upper pine wood, Peak of Cerro Potosi, Municipio de Galeana, July 21, 1935, Mueller 2257 (G, type; F, isotype)". TYPE: Mexico. Nuevo León, Galeana, Cerro Potosí, 24°52'N, 100°14'W, 21 July 1935, C.H. Mueller 2257 (holotype, GH-00043651!; isotypes, F-0044713F!, MICH-1192298 image!, NY-01364989!).

*Perennial herbs*, 14-33 cm tall. *Rootstock* 1.7-6.8 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed eglandular hairs 0.4-0.6 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae 2.2-3.5 cm long, 2.4-3.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.83-0.93], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with  $\pm$  appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic, 3.1-4.6 mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.26], 5-7-lobed in distal half [ratio secondary sinus length/middle segment length = 0.19-0.33]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in

age, with retrorse, appressed, eglandular hairs 0.4-0.7 mm long; stipules 4.7-11.9 mm long, 1.7-2.1 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on the margin, and sometimes on both surfaces. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio

cymule length/leaf length = 1.3-3.3]; peduncles 49-96(106) mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; bracteoles 5.9-9.9 mm long, 1-1.8 mm wide, lanceolate, whorled; pedicels 13-22 mm long, with retrorse, eglandular hairs 0.2-0.3 mm long and, rarely, patent, glandu-

lar hairs 0.2-0.4 mm long. Flowers actinomorphic. *Sepals* 6.1-6.2 mm long, 2.5-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.2-1.7 mm long [ratio mucro length/sepal length = 0.21-0.28], with  $\pm$  patent, eglandular hairs 0.5-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* 12.1-16.1 mm long, 5.7-8.5 mm wide, erect-patent, rounded, without claw, purple, hairy on the basal 1/2-3/4 of their adaxial surface, ciliate on the basal margin, with hairs 0.7-0.9 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.3-6.9 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-0.9 mm long; anthers 1.3-1.6 mm long, purple. Nectaries 5, hemispheric, with a tuft of hairs covering all of its surface. *Gynoecium* 4.9-7.8 mm long, purple. *Fruit* 19-20 mm long, erect, discharge of seed-ejection type; mericarps 4.2-4.3 mm long, 1.6-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callos, without a basal prong, brown, with erect-patent, eglandular hairs 0.6-0.7 mm long; rostrum 12.6-12.7 mm long, with a narrowed apex 0.8-0.9 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 2.1-2.2 mm long, with 5 glabrous lobes. *Seeds* unknown. Cotyledons not studied. Fig. 349.

Fig. 349. *Geranium potosinum*. a. Habit. b. Detail showing stem indumentum. c, d. Leaves, adaxial side. e. Stipules. f. Bracteoles. g. Flower, sepals and petals removed. h. Sepal, adaxial side. i. Petal, adaxial side. j. Stamen. k. Fruit. (Based on: a, b, e-k, Mueller 2257, F; c, Hinton & al. 20993, GH; d, Sharp 45738, MEXU).

Fig. 350. Distribution of *Geranium potosinum*.

*Pollen.* Ornamentation not studied.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from June to July.

*Distribution.* This species is endemic to Nuevo León and Coahuila, in northeastern Mexico (Fig. 350).

*Habitat.* *Pinus* L. and *Quercus* L. forests; 3000-3600 m.

*Additional specimens examined. Mexico.* COAHUILA: Arteaga, Sierra El Coahuilón, 25°14'N, 100°18'W, 17 June 1991, *Hinton & al.* 20993 (GH, IEB). NUEVO LEÓN: near top of Cerro Potosí, near Galeana, 24°52'N, 100°14'W, 16 July 1945, *Sharp* 45738 (MEXU).

*Discussion.* *Geranium potosinum* is known only from the type locality in the Cerro Potosí and a second locality in Coahuila, over 300 km to the north of the nearest locality recorded for the similar *G. tenue*. Petals of *G. potosinum* are purplish and longer than the white petals of *G. tenue*. The stipules and bracteoles of *G. potosinum* are broader and the sepal mucro is longer than in *G. tenue*, although with some overlap. The indumentum of *G. potosinum* is similar to that of *G. tenue*, although glandular hairs on peduncles, pedicels, and sepals are more frequent in *G. potosinum*. All these features should be considered with some caution, because there are so few specimens to evaluate.

**133. *Geranium niveum*** S. Watson, Proc. Amer. Acad. Arts 21: 421. 1886. TYPE LOCALITY: "Norogachi, in moist grassy openings (406) [collected by E. Palmer]". TYPE: Mexico. Chihuahua, Norogachi, 150 miles north of Batopilas, 29°14'N, 107°41'W, Nov. 1885, *E. Palmer* 406 (lectotype, designated by Moore 1943: 19, GH-00043644!; isotype, US-00100896 image!).

*Perennial herbs*, 26-49 cm tall. *Root-stock* 8-18.5 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons ab-

sent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 1.6-4.4 cm long, 2.1-5.6 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, sericeous on both surfaces, with appressed, eglandular hairs; segments 5, in more than 1 plane, middle segment rhombic (with linear-lanceolate lobes), 0.5-1.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.02-0.06], 3(5)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.30-0.64]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long; stipules 4.5-10.4 mm long, 1-2.6 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme with divaricate-monochasial branches or monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.6-9.9]; peduncles 15.6-84.6 mm long, with retrorse to uncinete eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.2-0.4 mm long; bracteoles 5.6-12.7 mm long, 0.9-2.9 mm wide, lanceolate, whorled; pedicels 21.7-54.6 mm long, with retrorse to uncinete eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 0.2-0.5 mm long. Flowers actinomorphic. *Sepals* (7.4)8.5-10.6 mm long, 2.8-4.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.2-2.5 mm long [ratio mucro length/sepal length = 0.13-0.26], sericeous, with antrorse, appressed, eglandular hairs 0.2-0.9 mm long and patent, glandular hairs 0.1-0.4 mm on the abaxial surface, glabrous adaxially. *Petals* (13.2)14.5-17.7 mm long, 6.7-11.8 mm wide, patent to retrorse, rounded, without claw, purple, hairy on the basal 1/3-1/2 of their adaxial surface, ciliate on the basal margin, with hairs 1-2 mm long. *Stamens* 10, both whorls bearing

anthers; filaments 9.1-15.6 mm long, lanceolate, purple, with eglandular hairs 0.3-0.7(1.2) mm long mostly on the margin; anthers 2.1-2.7 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8.5-11 mm long, purple. *Fruit* (23.4)29.5-35.6(42) mm long, erect, discharge of seed-ejection type; mericarps 3.9-5.3 mm long, 0.7-2.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.5-1.9 mm long and patent, glandular hairs 0.2-0.6 mm long; rostrum 13.7-27.4 mm long, with a narrowed apex (1.8)2.1-5.3 mm long, not twisted, with ± patent, eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 0.2-0.6 mm long; stigmatic remnants 4.6-7.5 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.9 mm long, 1.8-2.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 351.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 431).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from July to October.

*Distribution.* This species ranges through western Chihuahua, in northern Mexico (Fig. 352).

*Habitat.* Margins of cultivated fields, stream banks, meadows, *Pinus* L. and *Quercus* L. forests; 2000-2500 m.

*Additional specimens examined. Mexico.* CHIHUAHUA: 4 mi S of Creel, 27°45'N, 107°38'W, 4 Aug. 1960, *Straw & Forman* 1873 (MEXU); 6.3 mi N of Madera, 29°17'N, 108°8'W, 12 Aug. 1965, *Mertz* 256 (MEXU); along railroad tracks between Cuatrocientos and Las Barras de Babicora, 29°30'N, 108°1'W, 17 Aug. 1959, *Kruckeberg* 4935 (NY); base of Sierra Madre, 16 Sep. 1887, *Pringle* 1202 (F, GH, MEXU, NY); Bocoyna, 2.3 mi N of San Juanito road to El Alami-to-San Pedro, 27°58'N, 107°35'W, 2 Aug. 1977, *Bye & Weber* 7846 (GH); Bocoyna, E of Gonogochic, E of Creel, 27°50'N, 107°34'W, 21 Aug. 1973, *Bye* 4649 (GH); Bocoyna, ejido San Ignacio Arareco, E of Gonogochic, near José Lirio abandoned ranchito, 27°44'N, 107°37'W, 21 Aug. 1978, *Bye* 8724 (BM); Bocoyna, Huechochi, W

**Discussion.** *Geranium niveum* is characterized by its palmatisect leaves with five segments, these divided into three long and narrow lobes and sericeous on both surfaces. The cauline leaves are less lobed towards the apex of the plant and have a shorter petiole. In some cases, leaves at the distal nodes of the inflorescence are sessile and have three narrow and unlobed segments. The inflorescence in small specimens can be monochasial; however, well-developed plants have a dichasial inflorescence with two main branches and one 2-flowered cymule at the branch point. Each branch has a divaricate and usually geniculate, 2-flowered cymule per node. A dense indumentum of appressed eglandular hairs covers most of the plant, and is particularly dense on the leaf lamina, on young petioles, and abaxially on the sepals. Glandular hairs are restricted to the inflorescence; they are found on peduncles, pedicels, the base of sepals, the apex of mericarps, and the rostrum (although the narrow apex of the rostrum is glabrous). It is noteworthy that *G. niveum* has long, patent to retrorse petals, which have

long eglandular and entwined hairs on the basal half of the adaxial surface, as do many species of the Rocky Mountains (e.g., *G. caespitosum*). *Geranium niveum* shares palmatisection and sericeous leaves with *G. alpicola*, but those of *G. alpicola* are pilose only adaxially and sericeous abaxially. Additionally, the peduncles and pedicels of *G. alpicola* are covered with antrorse, appressed, eglandular hairs, while those of *G. niveum* have retrorse to uncinat e glandular hairs mixed with glandular hairs. Petals of *G. niveum* are longer than those of *G. alpicola* and adaxially hairy. Staminal filaments and anthers are longer in *G. niveum*, and the nectaries have a tuft of hairs at the apex; the nectaries of *G. alpicola* are glabrous.

*Perennial herbs*, 18-70 cm tall. *Rootstock* 6.6-12 mm in diameter, horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent or retrorse, eglandular hairs 0.3-1.4 mm long, and sometimes, patent, glandular hairs 1.5-1.7 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminas 5-11.5 cm long, 6.8-14.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.82-0.92], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 3.5-8.8(12) mm wide at the base [ratio segment width at the base/middle segment length = 0.07-0.16], (7)9-23-lobed in distal half [ratio secondary sinus length/middle segment length = 0.12-0.25]; petioles up to 33 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.4-0.9 mm long and, sometimes, patent, glandular hairs 1.1-1.5 mm long; stipules 3.7-13 mm long, 1.2-3.1 mm wide, linear-lanceolate, free, papery, brownish red, with eglandular and glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = (0.7)1.1-2.2]; peduncles 19-103 mm long, with patent to retrorse, eglandular hairs 0.2-1.4 mm long and, rarely, patent, glandular hairs 0.8-1.5 mm long; bracteoles 2.9-8.1 mm long, 0.5-0.9 mm wide, lanceolate, whorled; pedicels absent or 10-31 mm long, with patent to retrorse, eglandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* 6-10.4 mm long, 2.8-4.5 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1.3-2.9 mm long [ratio mucro

length/sepal length = 0.18-0.34], with antrorse, appressed eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.9-2.1 mm long on the abaxial surface, glabrous adaxially. *Petals* 11.6-16.1 mm long, 7.8-12.9 mm wide, erect-patent, rounded, without claw, purple, sometimes white, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.7-8.3 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.4 mm long; anthers 2.2-2.5 mm long, yellow or purple. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 5.6-9.8 mm long, green. *Fruit* 27-34.2 mm long, erect, discharge of seed-ejection type; mericarps 3.5-4.8 mm long, 1.8-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.2-0.9 mm long and, patent, glandular hairs 1.1-1.9 mm long; rostrum 17-31 mm long, with a narrowed apex 4.5-7 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.5 mm long and, rarely, patent, glandular hairs 1-1.2 mm long; stigmatic remnants 1.6-3.6 mm long, with 5 glabrous lobes. *Seeds* 2.3-3.2 mm long, 1.5-1.9 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 353, 354.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 427).

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from March to September.

*Distribution*. This species ranges through central and eastern U.S.A. and southeastern Canada (Fig. 355).

*Habitat*. Meadows, roadsides, deciduous and evergreen forests; 50-950 m.

*Representative specimens examined*. **Canada**. ONTARIO: at road cut-off of highway 401 with Salmon River, 44°12'N, 77°13'W, 30 May 1967, Baum 67-05-30-0 (DAO); Middlesex Co., Komoka, 42°57'N, 81°26'W, 22 May 1960, Minshall 4386

**Discussion.** *Geranium maculatum* has a horizontal rootstock giving rise to an erect aerial stem with a persistent rosette of leaves. The stem is naked up to the first branch point of the inflorescence, where a pair of opposite leaves is always present. The inflorescence is dichasially branched, with 2-flowered cymules on the lower nodes and an aggregate of cymules towards the apex of each branch. In these aggregates the pedicels are usually short or absent. *Geranium maculatum* shows a distinctive indumentum of long glandular hairs ending in a usually reddish narrow cell (this apical cell is of similar width to that of the basal cell). These hairs are always present on sepals and the mericarp apex, usually on stipules and bracteoles, and sometimes on petioles and peduncles. *Geranium maculatum* shows some affinity with *G. sylvaticum* and *G. erianthum*. The three species share a similar rootstock, inflorescence structure, and adaxially glabrous petals. *Geranium maculatum* has nectaries with a tuft of hairs at the apex (not glabrous as in the other two species), and a distinctive glandular indumentum. Additionally, *G. sylvaticum* and *G. erianthum* have cauline alternate leaves, not present in *G. maculatum*. *Geranium maculatum* also shows some similarities with *G. oreganum*. Both species share adaxially glabrous petals, hairy nectaries, and opposite leaves, but *G. oreganum* has longer petals and fruits, and a dense indumentum of glandular hairs on the pedicels (with an apical cell wider than the basal cell). All these species occur allopatrically in North America; *G. maculatum* is the most common perennial species of *Geranium* in the eastern U.S.A. (Jones & Jones 1943: 13).

A detailed account of the life history of *G. maculatum* is provided by Martin (1965). Willson & al. (1979) explored the adaptive aspects of the floral display in *G. maculatum*.

*Perennial herbs*, (15)40-80 cm tall. *Rootstock* 5-8.9 mm in diameter, horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-0.9 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminae 6-12 cm long, 7-14 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.78-0.90], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 7, in 1 plane, middle segment rhombic, 5-10 mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.15], 9-19-lobed in distal half [ratio secondary sinus length/middle segment length = 0.18-0.38]; petioles up to 35 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.2-0.7 mm long; stipules 8-12 mm long, 2-3 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflores-*

*cence* a dichasial cyme; cymules 2-flowered, solitary or, rarely, in aggregates at the top of each branch [ratio cymule length/leaf length = 3.3-4.9]; peduncles 45-110 mm long, with patent to retrorse, eglandular hairs 0.2-0.9 mm long and patent, glandular hairs 0.3-1.1 mm long; bracteoles 4-7 mm long, 1-1.3 mm wide, lanceolate, whorled; pedicels absent or 10-35 mm long, with patent to retrorse, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.3-1.1 mm long. Flowers actinomorphic. *Sepals* 8.6-11 mm long, 3.6-5 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1.5-2 mm long [ratio mucro length/sepal length = 0.19-0.24], with patent, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.3-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 13-24 mm long, 12-21 mm wide, erect-patent, rounded or slightly emarginate (notch ca. 0.5 mm deep), without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.5-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 8-10.8 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.6 mm long; anthers 2.5-3 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 6.9-10 mm long, purple. *Fruit* 35-52 mm long, erect, discharge of seed-ejection type; mericarps 4.5-5 mm long, 2.5-3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.3-0.8 mm long; rostrum 27-44 mm long, with a narrowed apex 4-6 mm long, not twisted, with patent, eglandular hairs 0.1-0.4 mm long and patent, glandular hairs 0.3-0.8 mm long; stigmatic remnants 3-6 mm long, with 5 glabrous lobes. *Seeds* 2.8-3 mm long, 2-2.1 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 356.

*Pollen.* *Geranium*-type (Aedo 2001a: 17).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from March to October.

*Distribution.* This species ranges from southern Washington and Oregon to northern California, in north-western U.S.A. (Fig. 357).

*Habitat.* Roadsides, moist meadows, slopes, deciduous and ever-green forests; 50-1500 m.

*Additional specimens examined. USA.*

**Discussion.** *Geranium oreganum* is a robust species similar to the sympatric *G. richardsonii* and *G. viscosissimum*, but it is easily distinguished from these species by its long, glabrous petals. It resembles other perennial species in the Rocky Mountains in its inflorescence structure leaf form and arrangement, and fruit characters. Differences between *G. oreganum* and *G. maculatum* are addressed in the discussion of the latter species. In *G. oreganum* glandular hairs are always present on the inflorescence, sepals, and mericarps; they are similar to glandular hairs of *G. richardsonii* and *G. viscosissimum*, but shorter than in *G. maculatum* and terminate in a broad, usually red cell. Records of this species from Canada (Douglas & al. 1989: 51; Scoggan 1978: 1046) are probably errors for *G. viscosissimum* or *G. ibericum* (Aedo 2001b: 16).

**The Mexicanum Group**—This group is characterized by its usually erect or ascending habit, its sometimes turnip-shaped rootstock, its usually opposite, palmatifid leaves and its 2-flowered cymules arranged in dichasial inflorescence. The petals are of medium size, erect-patent, without claw, and hairy only on the base.

**Discussion.** *Geranium mexicanum* has a vertical, turnip-shaped rootstock. The ascending aerial stem usually has one alternate leaf near the base or the middle, and 2-3 pairs of opposite, reduced cauline leaves distally. In some specimens, or at least in some herbarium fragments, this alternate leaf is not present. The inflorescence is terminal and dichotomously branched, although some cymules are borne directly on the rootstock. Among the most noticeable features of this species are its long peduncles and pedicels. Cymules of *G. mexicanum* are usually 2-flowered, although frequently cymules with 2, 3, or 4 flowers are found on the same specimen. The indumentum of *G. mexicanum* consists of eglandular hairs scattered on the stem, leaves, and inflorescence, and of glandular hairs usually restricted to the inflorescence. The glandular indumentum varies sometimes in the same specimen, and some cymules have few or no glandular hairs. *Geranium mexicanum* shares with *G. lozanoi* a general appearance, inflorescence structure, and leaf shape; however, *G. lozanoi* never has a glandular indumentum, and the eglandular hairs are short and retrorse-appressed (in *G. mexicanum* eglandular hairs are usually patent). *Geranium mexicanum* may be distinguished from *G. lozanoi* also by the shorter narrowed apex of the rostrum, petals, and sepals. Additionally, the petals are purplish in *G. mexicanum* and white in *G. lozanoi*. As Moore (1943: 36) pointed out, some

herbarium specimens of *G. seemanii*, a species well characterized by its short petals, were mislabeled as *G. mexicanum*.

The name *Geranium hirtum* Willd. ex Sprengel (1826: 72) is superfluous, because *G. mexicanum* Kunth was listed as a synonym in the protologue. It is also a later homonym. The epithet "hirtum" was used in *Geranium* by Burman (1759: 48) to name a taxon now transferred to *Pelargonium* L'Hér., and by Forsskål (1775: 123) for another taxon now transferred to *Erodium* L'Hér. Curiously, Knuth (1912: 147) applied *G. hirtum* Spreng. to collections from Colombia that are here included in *G. killipii*.

**137. *Geranium lozanoi*** Rose, Contr. U.S. Natl. Herb. 10(3): 108. 1906, ["lozani"]. TYPE LOCALITY: "U. S. National Herbarium no. 461465, collected by C. G. Pringle and F. Lozano near Buena Vista Station, Hidalgo, altitude 2,550 meters, 1904 (no. 8994)". TYPE: Mexico. Hidalgo, Buena Vista Station, 19°59'N, 98°33'W, 6 Aug. 1904, C.G. Pringle & F. Lozano 8994 (holotype, US-461465 image!; isotypes, BM!, CSPU, FI, GH, GOET, KI, LE!, NY!, P-00700630!, PR-375710!, UC-137764 image!, W!).

*Perennial herbs*, 31-43 cm tall. *Rootstock* 5-10 mm in diameter, ± vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* ascending to erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 3.6-7 cm long, 4.3-8.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.76-0.89], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic, 2.8-9.1 mm wide at the base [ratio segment width at the base/

middle segment length = 0.10-0.34], 9-16(23)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.32-0.49]; petioles up to 21 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; stipules 3.5-7 mm long, 1.4-3.4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, usually glabrous

adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.5-3.9]; peduncles (94)118-170(285) mm long, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long; bracteoles 4.2-7.6 mm long, 0.7-1.4 mm wide, lanceolate, whorled; pedicels 32-81 mm long, with retrorse, appressed, eglandular hairs 0.1-0.6 mm long. Flowers actinomorphic. *Sepals* (7.5)8.4-10.2(12.4) mm

long, 3.4-5.7 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.7-2.5 mm long [ratio mucro length/sepal length = 0.09-0.26], with antrorse,  $\pm$  appressed, eglandular hairs 0.3-1.2 mm long on the abaxial surface, glabrous adaxially. *Petals* 18.4-21.4(23.5) mm long, 9.8-14.7 mm wide, erect-patent, rounded or slightly emarginate (notch 0.4-0.7 mm deep), without claw, white, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.7-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7.7-10.4 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-1.6 mm long; anthers 2.3-2.6 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 8.6-10.9 mm long, unknown color. *Fruit* 28.3-40.4 mm long, erect, discharge of seed-ejection type; mericarps 4-5.5 mm long, 2.1-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.6 mm long; rostrum 17.4-27.4 mm long, with a narrowed apex 2.3-4.2 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long; stigmatic remnants 4.6-7.3 mm long, with 5 glabrous lobes. *Seeds* 2.8-2.9 mm long, 2.2-2.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 360.

Fig. 360. *Geranium lozanoii*. a. Habit. b. Leaf, adaxial side. c. Stipules. d. Bracteoles. e. Flower, sepals and petals removed. f. Sepal. g. Petal, adaxial side. h. Stamen. i. Fruit. j. Mericarp. k. Seed. (Based on: a, c, d, i-k, Pringle 8994, P; b, Moore & Wood 4881, GH; e-h, Moore 3505, GH).

Fig. 361. Distribution of *Geranium lozanoii*.

*Pollen.* Ornamentation not studied.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from July to September.

*Distribution.* This species is endemic to southern Hidalgo, in central Mexico (Fig. 361).

*Habitat.* Roadsides, furrows of corn fields, and meadows; 2300-2800 m.

*Additional specimens examined.* **Mexico.** HIDALGO: near Hacienda Cuyamaloya, 20°2'N, 98°32'W, 31 July 1947, Moore 3505 (GH); between Somoriel and Las Lajas, 20°2'N, 98°29'W, 5 Aug. 1905, Rose & al. 9208 (NY, P); Tulancingo, between rancho San Alejo and Santa Ana on road to Agua Blanca, 20°7'N, 98°19'W, 7 Sep. 1948, Moore & Wood 4881 (GH, MEXU).

*Discussion.* *Geranium lozanoi* is quite similar to *G. mexicanum* in general appearance but with longer, white petals and an eglandular indumentum. Other differences are discussed under *G. mexicanum*, an allopatric species ranging from Guanajuato to southern Durango. *Geranium lozanoi* is known only from southwestern Hidalgo; I did not locate the specimen *Arsène s.n.* (F) from northern Michoacán cited by Moore (1943: 49). *Geranium lozanoi* has sometimes been confused with *G. schiedeanum*, a sympatric species that is widespread in central Mexico. Both species share deeply divided leaves and long peduncles; however, the petals of *G. lozanoi* are white and longer (with some overlap). Although *G. schiedeanum* sometimes has white petals, this variation seems to be restricted to populations in Guerrero and Oaxaca, 250 km south of the range of *G. lozanoi*. Leaves of *G. lozanoi* are longer than those of *G. schiedeanum*, with wider lobes and middle segment base. Sepals and staminal filaments are longer, and the sepal mucro is shorter, in *G. lozanoi* than in *G. schiedeanum*. According to Moore (1943: 50), *G. lozanoi* is characterized by its sparse, very short, almost scale-like hairs. *Geranium schiedeanum* has longer (with some overlap) and more abundant hairs on stem, petioles, and inflores-

cences, but it is difficult to differentiate the shapes of eglandular hairs in both species. These hairs may be included in the "subulate" type of Payne (1978), which is common in *Geranium*. In *G. schiedeanum* some hairs have a circular basal portion and others a narrowly elliptic one. The second type appears under the microscope as "plane" or "scale-like", particularly if it is very short. In *G. lozanoi* most of the hairs seem to be of this second type.

---

**138. *Geranium crenatifolium*** H.E. Moore, Contr. Gray Herb. 146: 38. 1943. *Geranium crenatum* S. Watson, Proc. Amer. Acad. Arts 17: 334. 1882, nom. illeg., non Andrews, 1805. TYPE LOCALITY: "At Lerios, Coahuila (136)" ["collected chiefly by Dr. E. Palmer..."]. TYPE: Mexico. Coahuila, Lerios, 15 leagues E of Saltillo, 25°27'N, 100°41'W, 1880, E. Palmer 136 (lectotype, designated by Moore 1943: 39, GH-00043624!; isoelectotypes, K-000531450!, NY!, PI, US image!).

*Perennial herbs*, 18-44 cm tall. *Root-stock* 2.9-7.5 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy (rarely scapiform), not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs (0.3)1-2 mm long and patent, glandular hairs 0.1-0.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae 1.8-5 cm long, 2.4-6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.68-0.88], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular (and rarely glandular) hairs; segments 5, in 1 plane, middle segment subrhombic to obtriangular, 3.7-10.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.22-0.37], 5-11(16)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.10-0.28];

petioles up to 14 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs (0.3)1-1.7 mm long and patent, glandular hairs 0.1-0.5 mm long; stipules 5.8-19.2 mm long, 1.7-4.9 mm wide, lanceolate, free, papery, brownish red, with eglandular and, sometimes, glandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.6-5.9]; peduncles (19)53-114(150) mm long, with patent to retrorse, eglandular hairs (0.2)0.8-2 mm long and patent, glandular hairs 0.1-0.7 mm long; bracteoles 5-11.5 mm long, 0.8-1.9 mm wide, lanceolate, whorled; pedicels 12-37 mm long, with patent to retrorse, eglandular hairs (0.3)1.1-1.8 mm long and patent, glandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* 7.5-9.8 mm long, 2.5-5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-1.5(1.9) mm long [ratio mucro length/sepal length = 0.05-0.23], with ± patent, eglandular hairs (0.2)0.9-2.4 mm long and patent, glandular hairs 0.2-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (15.2)17.1-20.8 mm long, 8.1-14.4 mm wide, erect-patent, rounded or slightly emarginate (notch 0.5-1.1 mm deep), without claw, purple, rarely white, hairy on the base of both surfaces, ciliate on the basal margin, with hairs 0.5-1.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.4-9.7 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.5-1.5(2.2) mm long; anthers 1.6-3 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5.5-9.8 mm long, purple. *Fruit* 26.8-35.6 mm long, erect, discharge of seed-ejection type; mericarps 4.1-5.2 mm long, 1.6-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-1.3 mm long and patent, glandu-

lar hairs 0.1-0.6 mm long; rostrum 18.1-27.6 mm long, with a narrowed apex 2.4-5.8 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-1.2 mm long, and patent, glandular hairs 0.1-0.4 mm long; stigmatic remnants 2-3.4 mm long, with 5 glabrous lobes. Seeds 2.7-3 mm long, 1.7-1.8 mm wide, finely reticulate, uniformly

colored, brown, glabrous. Cotyledons with entire margin. Fig. 362.

*Pollen.* Ornamentation not studied.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from May to August.

*Distribution.* This species ranges from Durango to Nuevo León, in northern Mexico (Fig. 363).

*Habitat.* Roadsides, streams banks, alpine meadows, open shrubby hillsides, and *Abies* Mill., *Pseudotsuga* Carrière, *Pinus* L., and *Quercus* L. forests; 2200-3850 m.

**Discussion.** *Geranium crenatifolium* has a vertical rootstock and a  $\pm$  persistent leaf rosette. The aerial stem is erect, usually with 2-3 nodes of opposite leaves, and ends in a dichasially branched inflorescence. Yet, some specimens have cymules arising directly from the rootstock; occasionally, herbarium samples include only small plants of this stemless type. The indumentum composed of eglandular hairs is a distinctive feature of this species. Inflorescences, stems, and petioles have long, soft, patent eglandular hairs (and also shorter and usually retrorse ones). Short glandular hairs are also present. *Geranium crenatifolium* has long petals with hairs restricted to the base (on

both surfaces) and the basal margin. Staminal filaments have also eglandular hairs, some distinctively long. *Geranium crenatifolium* is widespread from southeastern Coahuila to Tamaulipas in the Sierra Madre Oriental. Moore (1951: 252) recorded this species from some localities in the Sierra Madre Occidental (southwestern Durango) 500 km towards the west. These specimens match collections from the main range of the species. Some features found in *G. crenatifolium* are shared by *G. trolliifolium*. Both species have long petals with the indumentum restricted to the base, glabrous nectaries, staminal filaments with long hairs, and long, soft, patent eglandular hairs on inflorescences and stems. *Geranium trolliifolium* differs in its very robust rootstock and usually bears an alternate leaf on the stem. Leaves of *G. trolliifolium* are longer than those of *G. crenatifolium* and have rhombic segments (those of *G. crenatifolium* are usually obtriangular and have fewer lobes). Bracteoles and eglandular hairs are shorter in *G. trolliifolium* than in *G. crenatifolium*, although with some overlap. Cymules of *G. crenatifolium* are 2-flowered, while those of *G. trolliifolium* are 2-6-flowered and sometimes umbel-like.

**139. *Geranium pringlei*** Rose, Contr. U.S. Natl. Herb. 10(3): 109. 1906. TYPE LOCALITY: "Type U. S. National Herbarium no. 461451, collected by C. G. *Perennial herbs*, 28-65 cm tall. *Rootstock* 5-10 mm in diameter, vertical,

not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 2-2.7 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae 3.6-4.8 cm long, 3.5-6.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.90], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with  $\pm$  appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic, 4.3-10 mm wide at the base [ratio segment width at the base/middle segment length = 0.16-0.31], 7-11-lobed in distal half [ratio secondary sinus length/middle segment length = 0.16-0.34]; petioles up to 19 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 1.3-2.5 mm long and rarely, patent, glandular hairs 0.2-0.3 mm long; stipules 6.8-10 mm long, 2.5-4.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2-3.4]; peduncles 106-170 mm long, with patent to retrorse, eglandular hairs (0.2)2-3 mm long and patent, glandular hairs 0.3-0.8 mm long; bracteoles 3.8-8.7 mm long, 1.2-1.6 mm wide, lanceolate, whorled; pedicels 15-28 mm long, with patent to retrorse, eglandular hairs 0.3-1.3 mm long and patent, glandular hairs 0.3-0.9 mm long. Flowers actinomorphic. *Sepals* 8.2-10.4 mm long, 3.4-5.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.1-1.7 mm long [ratio mucro length/sepal length = 0.12-0.18], with  $\pm$  patent, eglandular hairs (0.2)1.7-2.5 mm long and patent, glandular hairs 0.2-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 15-17.8 mm long, 9.7-15.4 mm wide, erect-patent, rounded or slightly emarginate (notch 1-2 mm deep), without claw, purple, hairy on

the base of both surfaces, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.5-8.4 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 1.1-2.8 mm long; anthers 2.5-2.7 mm long, purple. *Nectaries* 5, hemispheric, glabrous. *Gynoeceum* 6.2-8.7 mm long, purple.

*Fruit* 28-34 mm long, erect, discharge of seed-ejection type; mericarps 4-5 mm long, 1.8-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.7-1 mm long and patent, glandular hairs 0.5-0.9 mm long; rostrum 20-26.5 mm long,

with a narrowed apex 2.3-4.6 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.3-1.2 mm long; stigmatic remnants 1.6-2.5 mm long, with 5 glabrous or scattered hairy lobes. *Seeds* 2.4-3.1 mm long, 1.4-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 364.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to August.

*Distribution*. This species ranges through central Mexico (Fig. 365).

*Habitat*. Stream banks, meadows, and *Pinus* L. forests; 2000-3100 m.

*Additional specimens examined*. **Mexico**. ex Nov. Hispania, *Née s.n.* (MA). HIDALGO: Cuyamaloya Station, 20°2'N, 98°32'W, 4 Aug. 1906, *Pringle s.n.* (BC). MEXICO STATE: carretera libre Toluca-México D.F., un poco arriba del poblado La Marquesa, 19°17'N, 99°21'W, 26 July 1996, *Vibrans* 5774 (MEXU); entre El Oro y Via Victoria, 19°43'N, 99°56'W, July 1920, *Matuda & al.* 30927 (MEXU).

*Discussion*. *Geranium pringlei* resembles *G. crenatifolium* in habit, petal size and indumentum, and nectaries, but may be distinguished by some indumentum characters. Eglandular hairs on stems, petioles, peduncles, sepals, and staminal filaments are noticeably longer in *G. pringlei*, although with some overlap. *Geranium*

Fig. 365. Distribution of *Geranium pringlei*.

*pringlei* lacks glandular hairs on the stem base (they only appear in the inflorescence); the glandular hairs on the fruit (especially on the rostrum) are longer than in *G. crenatifolium*. Although petals of both species are quite similar, those of *G. pringlei* seem to have shorter and fewer hairs. Also, *G. pringlei* has longer peduncles. Leaf segments in *G. pringlei* are rhombic, and the leaf surface is sparsely pilose, whereas *G. crenatifolium* usually has obtriangular leaf segments and a denser indumentum. The inflorescence of *G. pringlei* is dichasial in most of the specimens of the type collection and in the other two samples. Nevertheless, in some duplicates of the type some of the peduncles occur singly at lower nodes (Moore 1943: 41). Among the nine duplicates of the holotype studied, only the NY isotype shows a single cymule arising directly from the rootstock; however, in *G. crenatifolium* single cymules seem to be fairly frequent. The ranges of these species do not overlap; *G. pringlei* occurs in a zone about 400 km to the south of the southernmost localities of *G. crenatifolium*.

**The *Potentillifolium* Group**—This group is characterized by its usually ascending or erect habit, its turnip-shaped rootstock, its opposite, palmatifid leaves and its 1- or 2-flowered cymules arranged in monochasial inflorescence. The petals are of medium size, erect-patent, without claw, and hairy only on the base.

**Discussion.** *Geranium potentillifolium* is a spreading or ascending plant arising from a robust rootstock. The rootstock has a  $\pm$  long and branched apical portion, which is joined to a vertical and turnip-shaped part. Sometimes secondary and smaller turnip-shaped segments are joined to the distal portion of this turnip-shaped part. The indumentum of *G. potentillifolium* is composed of eglandular hairs, which are usually patent to partially retrorse on stem and inflorescences. The hairs are abundant, but the vesture is not sericeous, except abaxially on the leaves, especially when young. In mature leaves this indumentum is not as dense and appressed as in *G. alpicola*. The leaf indumentum is spreading adaxially, with suberect to appressed hairs. As pointed out by Moore (1943: 54), there is considerable variation in size and division of the leaves. The leaves are deeply palmatifid, with usually five segments divided in long and narrow lobes. The lobes often have revolute margins. Some specimens have an unusually long sepal awn (e.g., *Moore* 1253, GH; *Rose & Painter* 7923, NY), but otherwise they agree very well with *G. potentillifolium*. Basal leaves are present in few herbarium specimens and always in a very low number.

*Geranium potentillifolium* shares with *G. bellum* 1-flowered cymules and deeply divided leaves. Yet, the leaves of *G. potentillifolium* have narrower segments, usually with longer and narrow lobes, that are sericeous abaxially, but in *G. bellum* the lobes are only pilose. The petals of *G. potentillifolium* are purplish but usually white in *G. bellum*. The distribution areas of the two species overlap only in a small region. *Geranium potentillifolium* is found in central Mexico, with some isolated populations in southern Puebla and Oaxaca that are indistinguishable from those of central Mexico. All have lavender petals, short anthers, short peduncles, and leaves that are  $\pm$  tomentose abaxially.

Moore (1943: 53) designated a copy of the drawing cited in the protologue from *Icones florum mexicanarum ineditae* by Sessé and Mociño (De Candolle 1874, tab. 148) as type of *G. potentillifolium*; however, the original drawing (not available in Moore's time) is the accurate choice. The epitype is a specimen at G from Sessé & Mociño herbarium, without any indication of locality, labeled as "herb. Thibaud". According to Burdet (2008), E. Thibaud assembled a herbarium with plants donated by Cavanilles and by Ruiz and Pavón during his stay at Madrid. This herbarium was partially bought by A.P. Candolle. Thus, it is evident that the specimen in Candolle's herbarium (G-DC) is a plant from the Sessé and Mociño expedition obtained by Thibaud in Madrid. At MA there are nine sheets of *G. potentillifolium* in the separate Sessé & Mociño herbarium, four of them labeled as "*Geranium sibiricum*." At BM there are three Sessé & Mociño specimens, all with a handwritten note on the back of the sheet: "Mexico. Herb. Pavon", one labeled as "*Geranium dissectum*/NE", and other "*Geranium* sp. nova/de mexico". These specimens were sold by Pavón to Lambert in 1842; part of the Lambert herbarium is now incorporated in the general collection at BM. At F there is a sheet (plus three fragments) labeled "*Geranium sibili-*

*cum*/NE"; none include indication of the collecting locality. The specimens at BM, F, and MA are considered isoeotypes. For information concerning the Sessé & Mociño herbarium, see McVaugh (2000).

**141. *Geranium bellum*** Rose, Contr. U.S. Natl. Herb. 10(3): 108. 1906. TYPE LOCALITY: "Type U. S. National Herbarium no. 395386, collected by J. N. Rose and Robert Hay on Sierra de Pachuca, Hidalgo, July 21 and 22, 1901 (no. 5618)". TYPE: Mexico. Hidalgo, Sierra de Pachuca, 20°11'N, 98°43'W, 21-22 July 1901, *J.N. Rose & R. *Perennial herbs*, 10-42 cm tall. *Rootstock* 4.2-15.2 mm in diameter,  $\pm$  vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with  $\pm$  patent, eglandular hairs 0.9-1.9 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae 1.5-4.2 cm long, 1.7-5.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.78-0.95], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with scattered,  $\pm$  appressed, eglandular hairs on the adaxial surface, and densely hairy abaxially; segments 5, in 1 plane, middle segment rhombic (with linear-lanceolate lobes), 1.5-4.5 mm wide at the base [ratio segment width at the base/middle segment length = 0.09-0.21], 7-14(17)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.27-0.49]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.5-1.7 mm long; stipules 2.6-6.9 mm long, 0.6-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flow-

ered, solitary [ratio cymule length/leaf length = 1.4-3.9]; peduncles 27-85(115) mm long, with patent to retrorse, eglandular hairs 0.4-1.4 mm long; bracteoles 3.7-7.9 mm long, 0.5-0.8 mm wide, linear-lanceolate, opposite; pedicels 13-59 mm long, with patent to retrorse, eglandular hairs 0.4-1.5 mm long. Flowers actinomor-

phic. *Sepals* 5-7.9(9.6) mm long, 2-3.6 mm wide, lanceolate, smooth, not accrescent, nerves 3(5), mucro 0.5-2 mm long [ratio mucro length/sepal length = 0.10-0.20], with antrorse to patent, eglandular hairs 0.4-1.8 mm long on the abaxial surface, glabrous adaxially. *Petals* (10.4)11.5-15.5(16) mm long, 6-10.8 mm wide, erect-patent,

rounded, without claw, white, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.4-0.9 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4-6.6 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-1.3(1.8) mm long; anthers 1.7-2.2 mm long, yellow. Nectaries 5, hemispheric, usually glabrous. *Gynoecium* 9.7-9.2 mm long, yellow. *Fruit* 25-33 mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.5 mm long, 1.8-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-1.7 mm long; rostrum 16.8-23.5 mm long, with a narrowed apex 1.5-3.7 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.5-1.2 mm long; stigmatic remnants 2.5-4.5 mm long, with 5 glabrous lobes. *Seeds* 2.5-3 mm long, 1.6-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 368.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to October.

*Distribution*. This species ranges through central Mexico (Fig. 369).

*Habitat*. Meadows, and *Abies* Mill., *Pinus* L., and *Quercus* L. forests; 2000-3200 m.

*Discussion.* *Geranium bellum* is similar to *G. potentillifolium* in habit, rootstock, and indumentum. The indumentum of *G. bellum* is composed of eglandular hairs, usually longer than those of *G. potentillifolium*, especially on stem and mericarps. Mature leaves of *G. potentillifolium* are sericeous abaxially, while those of *G. bellum* are only densely hairy (i.e., the hairs more abundant than adaxially but the indumentum never sericeous). The anthers of *G. bellum* are always longer than those of *G. potentillifolium*, although with some overlap. Petals of *G. bellum* are white, sometimes with darker veins, and purplish in *G. potentillifolium*. *Geranium bellum* is distributed from central Guanajuato to Hidalgo and northern México state. *Geranium potentillifolium* has a more southerly range, which overlaps with *G. bellum* in southwestern Hidalgo and northern México. The type of *G. bellum* was collected in the Sierra Pachuca in southwestern Hidalgo, where both *G. bellum* and *G. potentillifolium* grow. Unfortunately, this original collection (*Rose & Hay*

5618) is heterogeneous. At NY there are two duplicates of *Rose & Hay 5618* that have discolored petals but with purplish margins, short anthers, and abaxially sericeous leaves. They were identified by Moore (1943: 50-51) as *G. potentillifolium* and are to be excluded from the type collection of *G. bellum*. The holotype of *G. bellum* at US has white petals, and the leaves are not sericeous (anther are not present in this specimen); it agrees with the *Rose's* (1906) description in the protologue.

OAXACA: Juxtla-huaca, San Juan Mixtepec, Cerro Peña Cerrada de Biga a 6 km de La Batea a Santo Domingo Yosoñama, 17°18'N, 97°51'W, 8 Aug. 1987, *Sánchez* 26 (IEB).

*Discussion.* *Geranium andicola* is similar to *G. potentillifolium* and *G. bellum* in habit, rootstock, and indumentum. The indumentum of *G. andicola* is composed of short eglandular hairs, usually retrorse and sometimes appressed, and present on stems, petioles, and inflorescences. Leaves of *G. andicola* are less deeply divided than in *G. potentillifolium* and have broader segments and lobes. The abaxial surface is more hairy than the adaxial one but never sericeous. *Geranium andicola* has always white petals, like *G. bellum*, but short anthers, like *G. potentillifolium*. The most distinctive feature of *G. andicola* is its longer cymules, especially the longer pedicels, although with some overlap with *G. bellum* and *G. potentillifolium*. In two specimens of *G. andicola* both 1-flowered and 2-flowered cymules were found, although in general specimens have only 1-flowered cymules. *Geranium andicola* is found in western Guatemala and adjacent Chiapas (Mexico); it has been collected once in Oaxaca. Plants from Chiapas have peduncles shorter than those of Guatemala but otherwise agree with *G. andicola*. The specimens studied have few well-developed fruits and mature seed. I agree with Moore (1943: 61)

that the two varieties described by Loesener are only variants with more or less long cymules that are linked by many intermediate forms.

Cotyledons with entire margin. Fig. 372.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 431).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to November.

*Distribution*. This species ranges through central and southern Mexico (Fig. 373).

*Habitat*. Margins of cultivated fields, moist rocky slopes, grassland, and *Abies* Mill., *Pinus* L., and *Quercus* L. forests; 1500-3600 m.

*Representative specimens examined*.

**Mexico.** GUERRERO: Chilpancingo de los Bravos, Ixtamalco, 18 km W of Chilpancingo, on rd to Olmiterni, 17°32'N, 99°40'W, 6 June 1985, *Thomas & Contreras* 3712 (NY); Chichihualco, a 25 km al W Xochipala, camino Filo del Caballo, 17°39'N, 99°42'W, 12 June 1982, *Martínez* 739 (MEXU). *Discussion*. *Geranium schiedeanum* is one of the most common species of cranesbills in central Mexico. It is sympatric and sometimes confused with the similar *G. potentillifolium*. The rootstock of *G. schiedeanum* is like that of *G. potentillifolium* with a vertical and turnip-shaped part, which is joined distally to secondary and smaller turnip-shaped segments. The leaf blades of *G. schiedeanum* are less deeply divided and have an abaxial indumentum not as dense as in *G. potentillifolium*. The peduncles of *G. schiedeanum* are noticeably long; there is little overlap in measurements with those of *G. potentillifolium*. Additionally, *G. schiedeanum* has 2-flowered cymules, whereas *G. potentillifolium* has 1-flowered ones; however, occasionally some 1-flowered cymules are present in plants of *G. schiedeanum*. The petals and staminal filaments of *G. schiedeanum* are longer than those of *G. potentillifolium*, although with some overlap, but the anthers of *G. schiedeanum* exceed those of *G. potentillifolium*. As Moore (1943: 58) pointed out, several species said to be similar to *G. schiedeanum* have been recognized, but the characters intergrade sufficiently to consider them as variants of a single variable species. Among these segregates, *G. arsenianum* is probably the most striking because of its dense indumentum; however, density of indumentum is a variable feature in *G. schiedeanum* that

Fig. 373. Distribution of *Geranium schiedeanum*.

does not show any correlation with other characters or geography. It is noteworthy that petals of plants from the southern part of the range of *G. schiedeana* (Guerrero and Oaxaca) are white or pinkish instead of purplish, but no additional features distinguish these populations from those of other parts of the range.

**144. *Geranium goldmanii*** Rose ex Hanks & Small in Underw. & Britton (eds.), N. Amer. Fl. 25(1): 17. 1907. TYPE LOCALITY: "Type collected at Teopisca, Chiapas, Mexico, May 7, 1904, E. A. Goldman 946". TYPE: Mexico. Chiapas, Teopisca, 16°32'N, 92°28'W, 7 May 1904, E.A. Goldman 946 (holotype, US-00100920 image!).

*Perennial herbs*, 24-60 cm tall. *Root-stock* 4.5-10.6 mm in diameter,  $\pm$  vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, hirsute, with patent, eglandular hairs (0.4)1-1.7 mm long. *Basal leaves* few, not long persistent, cauline leaves opposite; leaf laminae 1.9-3.7 cm long, 2.4-4.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.79-0.93], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with  $\pm$  appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic, 1.6-4.9 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.30], (7)9-13(17)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.19-0.43]; petioles up to 9 cm long, without abscission zone, terete, not swollen, not deflexed in age, hirsute, with patent, eglandular hairs (0.6)1.3-1.9 mm long; stipules 2.4-8.7 mm long, 0.8-2.4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme;

cymules 2-flowered, solitary [ratio cymule length/leaf length = 3-5.2(12)]; peduncles (83)109-155(178) mm long, hirsute, with patent, eglandular hairs (0.2)1-1.6 mm long; bracteoles 2.6-6.4 mm long, 0.4-0.9 mm wide, linear-lanceolate, whorled; pedicels 11-69 mm long, hirsute, with patent, eglandular hairs 0.3-1.5 mm long. Flowers actinomorphic. *Sepals* (6.3)6.9-8(10.3) mm long, 2.2-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.9-2.1 mm long [ratio mucro length/sepal length = 0.13-0.22], glabrous except for some patent, eglandular hairs 0.7-1.6 mm long on the veins of the abaxial surface, glabrous adaxially. *Petals* (11.5)13.7-16.1(18.2) mm long, 6.3-10.6 mm wide, erect-patent, rounded, without claw, purple, hairy on the base of their adaxial surface, ciliate on the basal margin, with hairs 0.4-0.9 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5-7.1 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-1.2 mm long; anthers 1.4-2 mm long, yellow. Nectaries 5, hemispheric, usually glabrous. *Gynoe-cium* 5.4-8.1 mm long, purple. *Fruit* 25-29.4 mm long, erect, discharge of seed-ejection type; mericarps 3.3-4.9 mm long, 1.5-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.8 mm long; rostrum 16-20.5 mm long, with a narrowed apex 1.4-2.9 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.8 mm long; stigmatic remnants 3.2-5.1 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.2 mm long, 1.6-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 374.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to November.

*Distribution*. This species ranges through Oaxaca and Chiapas, in southern Mexico (Fig. 375).

*Habitat*. Meadows, stream banks, rocky slopes, and *Liquidambar* L., *Persea* Mill., *Pinus* L., and *Quercus* L. forests; 1600-2500 m.

*Additional specimens examined*. **MEXICO**. **Discussion.** *Geranium goldmanii* shares with *G. schiedeanum* a similar habit, long peduncles, 2-flowered cymules, and purplish petals. Underground parts of *G. goldmanii* are poorly collected, but the available fragments suggest that it has a rootstock similar to that of *G. schiedeanum*. As Moore (1943: 52) pointed

out, *G. goldmanii* is distinguishable from *G. schiedeanum* by the longer and more rigid hairs of the stem base, petioles, peduncles, and sepals. Sepals of *G. goldmanii* are glabrous, except for some long hairs on the veins abaxially, whereas in *G. schiedeanum* the abaxial surface is covered with hairs that are longer on the nerves. Additionally, in *G. goldmanii* the bracteoles, sepal mucro, petals, and staminal filaments are shorter than in *G. schiedeanum*, although with some overlap. The ranges of the two species overlap somewhat only in central Oaxaca. The western populations of *G. andicola* reach central Chiapas and there are sympatric with *G. goldmanii*. Both species share long peduncles, but *G. andicola* is distinguished from *G. goldmanii* chiefly by its 1-flowered cymules and white petals. Additionally, *G. andicola* has shorter hairs stem, petioles, and peduncles although with some overlap. *Geranium goldmanii* was apparently first collected by Mociño. There is a specimen at MA (with a duplicate at F) labeled only as "*Geranium violaceum* / NE" [Nueva España]. According to Arias (1968: 194, 199), Mociño spent about two months in Chiapas towards the end of 1798, during his return from Guatemala to Mexico. It seems to be probable that the specimen was collected at that time.

Fig. 375. Distribution of *Geranium goldmanii*.

**The *Hernandesii* Group**—This group is characterized by its ascending to erect habit, its not turnip-shaped rootstock, its opposite, palmatifid leaves and its usually 2-flowered cymules arranged in monochasial inflorescence. The petals are of medium size, usually erect-patent, without claw, and usually hairy on 1/4 to 3/4 of their adaxial surface.

**Perennial herbs**, 29-83 cm tall. **Rootstock** 12-19 mm in diameter, vertical, not tuberculate, not turnip-shaped, unknown roots. **Stem** erect or ascending, leafy, not rooting at nodes, stolons absent, without veg-

etative stems, with patent to retrorse, eglandular hairs 0.4-1.9 mm long. **Basal leaves** few, not long persistent, cauline leaves opposite; leaf laminas 4.8-9.4 cm long, 5.2-9.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.81-0.96], polygonal (medium and upper hastate) in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular hairs; segments 3-5, in 1 plane, middle segment rhombic, 4.8-12(15.2) mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.35], 7-10(16)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.05-0.19]; petioles up to 21 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.4-2 mm long; stipules 4.4-10 mm long, 1.3-2.5 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.3-3.8]; peduncles (67)111-222(240) mm long, with patent to retrorse, eglandular hairs 0.7-1.4 mm long; bracteoles 3.4-10.8 mm long, 0.4-1.3 mm wide, lanceolate, whorled; pedicels 20-96 mm long, with patent to retrorse, eglandular hairs 0.2-1.4 mm long. Flowers actinomorphic. **Sepals** (7.7)8-9.9 mm long, 3.1-4.6 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro (2.6)2.8-4.8 mm long [ratio mucro length/sepal length = 0.31-0.50], with antrorse to patent, eglandular hairs 0.7-1.4 mm long on the abaxial surface, glabrous adaxially. **Petals** 14-16.8(17.2) mm long, 5.9-12.4 mm wide, erect-patent, rounded or slightly emarginate (notch 0.5-1.2 mm deep), without claw, white, rarely pink, hairy on the basal 1/2-3/4 of their adaxial surface, ciliate on the basal margin, with hairs 0.7-1.5 mm long. **Stamens** 10, both whorls bearing anthers; filaments 6.6-11.3 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the

proximal half, with hairs 0.4-1.4 mm long; anthers 1.6-2.2 mm long, blue. **Nectaries** 5, hemispheric, glabrous. **Gynoecium** 6.2-10.3 mm long, purple. **Fruit** 30.8-45.6 mm long, erect, discharge of seed-ejection type; mericarps 3.8-5 mm long, 2.2-3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.9-1.3 mm long; rostrum 23.2-33.6 mm long, with a narrowed apex (2.8)3.9-4.8(7.6) mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.5-0.9 mm long; stigmatic remnants 3.6-7.2 mm long, with 5 glabrous lobes. **Seeds** 2.6-3.5 mm long, 1.7-2.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 376.

**Pollen.** *Geranium*-type (Bortenschlager 1967: 433).

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from June to October.

**Distribution.** This species ranges through central Mexico (Fig. 377).

**Habitat.** Rocky slopes, pastures, and *Pinus* L. and *Quercus* L. forests; 1650-2600 m.

**Additional specimens examined. Mexico.** HIDALGO: Acuatla, 19°20'N, 98°51'W, *Altamirano 126* (MEXU); Cerro de los Pitos, 19°55'N, 98°44'W, 22 July 1951, *Matuda s.n.* (MEXU); El Chico, 20°13'N, 98°44'W, Sep. 1927, *Lyonnet 122* (BM, GH, MEXU, MO, NY); Tizapán, San Ángel, 20°39'N, 98°35'W, 11 Oct. 1928, *Saint Pierre 2143* (P). **Discussion.** *Geranium hernandesii* is a robust plant with a more or less erect stem and eglandular indumentum; it has long peduncles, long petals, and a long sepal mucro. The underground parts remain mostly unknown, although a stout vertical rootstock is apparently present. The deciduous basal leaves, seen on only a few specimens, have five segments and a polygonal outline; the middle and distal cauline leaves have three segments and are hastate. The lateral segments of leaves of *G. hernandesii* are usually shorter than the middle

Fig. 377. Distribution of *Geranium hernandesii*.

one and have basal lobelets. Cymules of *G. hernandesii* are longer than those of *G. deltoideum* owing to the longer peduncles and pedicels, and the sepals are also longer and have a longer mucro. In addition, the petals are also longer in *G. hernandesii* than in *G. deltoideum* and bear long hairs adaxially; they are usually erect-patent, although in some herbarium specimens they seem to be almost patent. The indumentum is always eglandular, and the hairs are usually longer than those of *G. deltoideum*, although with some overlap. The collection Rzedowski 26210 (CAS, MICH, NY) from Jalisco (Mexico) is unusual. The plants match typical representatives of *G. hernandesii* in the leaves, the long petals (15 mm long), long peduncles (up to 170 mm long), long sepal mucro (4 mm long), and glabrous nectaries; however, glandular hairs are present on the peduncles, pedicels, and sepals. This gathering is provisionally identified as *G. hernandesii*. Additional field work in the northwestern part of the range of *G. hernandesii* may reveal the extent of variability.

Originally, Moore (1943: 66) considered *G. aristisepalum* a separate species; yet, after examining a collection of *G. hernandesii* by Sessé & Mociño at F, Moore (1951: 250) reconsidered and included *G. aristisepalum* within *G. hernandesii*. Moreover, he pointed out that "those specimens to which I formerly applied the name of *G. Hernandesii* now seem to be no more than a southern phase of the more northern *G. deltoideum*". This interpretation is followed by Rzedowski & Rzedowski (1995: 16-19) and also in this work.

Moore (1943: 66) designated a copy of the drawing cited in the protologue from *Icones florum mexicanarum ineditae* by Sessé & Mociño (De Candolle 1874, tab. 147) as type of *G. hernandesii*; however, the original drawing (not available at Moore's time) is a more accurate choice. The other original element mentioned by De Candolle (1824: 641) is the drawing

published by Hernández (1649: 293 fig. 2); however, this figure shows a plant with the leaves very deeply divided and the basal segments well developed, which differs considerably from present concept of *G. hernandesii*. The epitype is a specimen at MA in the Sessé & Mociño herbarium. It is not mentioned in the protologue but likely the basis for the drawing selected as type.

Trelease (1888: 76) recorded *G. hernandesii* from Huachuca mountains, Arizona (U.S.A.). The voucher (Lemmon 2651) for this record was not located; however, according to the key and description provided by Trelease, the specimens he saw may be *G. caespitosum* or perhaps *G. wislizeni*, both found in this area. Surprisingly, Knuth (1912: 196) cited this name in the synonymy of *G. mexicanum* as "*G. Hernandezii* Trelease".

*Perennial herbs*, 29-75 cm tall. *Rootstock* 3.9-14.9 mm in diameter, vertical, not tuberculate, not tur-

nip-shaped, unknown roots. *Stem* prostrate to ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-1 mm long. *Basal leaves* few, not long persistent, cauline leaves opposite; leaf laminae 2.3-8.7 cm long, 2.5-9.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.70-0.89], polygonal (medium and upper hastate) in outline, base cordate (medium and upper  $\pm$  truncate), not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular hairs and rarely glandular hairs; segments 3-5, in 1 plane, middle segment rhombic, 3.8-10.6(17.9) mm wide at the base [ratio segment width at the base/middle segment length = 0.20-0.38], 7-11(19)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.09-0.19]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.4-1.7 mm long; stipules 3.4-11.4 mm long, 0.9-2.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1-5.5]; peduncles (12)21-73(89) mm long, with patent to retrorse, eglandular hairs 0.1-0.7 mm long and, usually, patent, glandular hairs 0.2-0.5 mm long; bracteoles 2-6.8 mm long, 0.3-1.2 mm wide, lanceolate, whorled; pedicels (3)12-33 mm long, with patent to retrorse, eglandular hairs 0.1-0.7 mm long and, usually, patent, glandular hairs 0.2-0.5 mm long. Flowers actinomorphic. *Sepals* 5.3-7.4(8.1) mm long, 2.2-4.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.6-1.7(2.5) mm long [ratio mucro length/sepal length = 0.10-0.32], with antrorse to patent, eglandular hairs 0.3-1.3 mm long and patent, glandular hairs 0.2-0.4 mm on the abaxial surface, glabrous adaxially. *Petals* 8-13(13.9) mm long, 3.9-10.3 mm wide, pat-

ent, rounded or slightly emarginate (notch 0.5-1.7 mm deep), without claw, white to pink, hairy on the basal 1/2-3/4 of their adaxial surface, ciliate on the basal margin, with hairs 0.7-1.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.1-11.1 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate

on the proximal half, with hairs 0.2-0.9(1.5) mm long; anthers 1-1.9 mm long, purple. Nectaries 5, hemispheric, usually with a tuft of hairs covering all of its surface. *Gynoecium* 5.2-13 mm long, purple. *Fruit* 19.9-32.5 mm long, erect, discharge of seed-ejection type; mericarps 3.2-4 mm long, 1.6-2.1 mm wide, without a strand of

fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.7 mm long and, usually, patent, glandular hairs 0.3-0.4 mm long; rostrum 12-21.4 mm long, with a narrowed apex (2.1)2.4-4.2(4.8) mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long and, usually, patent, glandular hairs 0.2-0.4 mm long; stigmatic remnants 2.6-6.2 mm long, with 5 glabrous lobes. *Seeds* 2.1-2.5 mm long, 1.3-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 378.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from Sonora to Guerrero, in western Mexico (Fig. 379).

*Habitat*. Roadsides, cliff bases, moist ravines, meadows, and *Abies* Mill., *Pinus* L., *Pseudotsuga* Carrière, and *Quercus* L. forests; 850-3300 m.

*Representative specimens examined*.

*Discussion.* *Geranium deltoideum* is similar to *G. hernandesii*. The leaves of *G. deltoideum* are like to those of *G. hernandesii* in shape although shorter. The indumentum of *G. deltoideum* is composed of short and usually patent eglandular hairs on stems, petioles, and inflorescences; glandular hairs are almost always present on the inflorescence. The peduncles, pedicels, sepal mucro, and petals of *G. deltoideum* are shorter than those of *G. hernandesii*. The nectaries of *G. deltoideum* are covered with hairs over the entire surface, whereas those of *G. hernandesii* are glabrous. As noted above, some errors in nomenclature and circumscription were corrected by Moore (1951: 250). *Geranium deltoideum* is distributed over a large area of Mexico with more than 1500 km between the northernmost localities in Sonora and the southernmost in Guerrero. Within this range, two similar but very local and poorly known species, *G. hystricinum* and *G. gentryi*, also occur. *Geranium deltoideum* differs from *G. hystricinum* by its longer petals and its well-developed narrowed rostrum apex. *Geranium*

*gentryi* and *G. deltoideum* share petals of similar length and a well-developed narrowed rostrum apex; however, *G. gentryi* has erect-patent, deep purplish petals, with shorter and less spreading hairs adaxially, and glabrous nectaries. The leaves of *G. deltoideum* almost always lack glandular hairs, but those of *G. gentryi* are always glandular-hairy. According to Moore (1943: 70), *G. sublaevispermum* resembles *G. deltoideum* in leaf shape, petals, and indumentum. He suggested that *G. sublaevispermum* could be differentiated by its shorter peduncles, pedicels, and fruit, and because its seeds are blackish and finely reticulate. All these characters fall into the variability of *G. deltoideum*, and *G. sublaevispermum* is here considered conspecific.

**147. *Geranium gentryi*** H.E. Moore, Contr. Gray Herb. 146: 74, pl. 1 fig. 1, pl. 5 fig. 6. 1943. 1.5-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.5-0.8 mm long; rostrum 17.1-20.6 mm long, with a narrowed apex 4.3-5.3 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long and, usually, patent, glandular 0.6-0.7 mm long; stigmatic remnants 2.6-2.9 mm long, with 5 glabrous lobes. *Seeds* 2.3-2.5 mm long, 1.2-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 380.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in March.

*Distribution*. This species is endemic to southern Sonora, in north-western Mexico (Fig. 381).

*Habitat*. Stream banks; ca. 1000 m.

*Discussion*. *Geranium gentryi* is known only from the incomplete type specimens obtained in southern Sonora, Mexico. Although the basal parts are not known, the species appears to be perennial, given its robust stature. Only cauline leaves are present in the type collection; these have mostly three segments, but some leaves have five segments (the two basal ones not well developed). This suggests that *G. gentryi* may have basal leaves with five segments, as does *G. deltoideum*. *Geranium gentryi* shares with *G. latilobum* and *G. hystricinum* a glandular indumentum on stems, leaves, and inflorescences; it differs from these in its larger and purplish petals. The adaxial indumentum of the petals is restricted to the basal quarter (sometimes third), whereas in *G. latilobum* and *G. hystricinum* the hairs are longer and occur over almost the entire petal. The narrowed apex of the fruit rostrum is well developed in *G. gentryi*, but it is shorter or absent in the other two species.

**148. *Geranium latilobum*** H.E. Moore, Contr. Gray Herb. 146: 70, pl. 3 fig. 15. 1943. TYPE LOCALITY: "MEXICO: Jalisco: streamside, Arroyo del Notoguio, San Sebastian, 1500 m., Feb. 13, 1927, Mexia 1671 (G, type; F, M, NY, isotypes)". TYPE: Mexico. **Discussion.** *Geranium latilobum* is a rare species known from only a few localities in Durango and Jalisco (Mexico). The incomplete material collected does not permit a full reconstruction of the basal part of the plant (rootstock, basal leaves). *Geranium latilobum* is quite similar to *G. deltoideum* in leaf outline, petal size, sepal mucro length, and peduncle length; it differs in the longer eglandular hairs on stems, petioles, and inflorescences. Moreover, the glandular indumentum of *G. latilobum* is

Fig. 382. *Geranium latilobum*. a. Flowering branch. b. Rootstock. c. Detail showing stem indumentum. d, e. Details showing adaxial indumentum of leaf segment. f. Stipules. g. Bracteoles. h. Flower, sepals and petals removed. i. Sepal. j. Petal. k. Stamen. l. Fruit. m. Mericarp. n. Seed. (Based on: a-c, e-n, *Mexia* 1671, BM; d, *Breedlove* 4263, CAS).

Fig. 383. Distribution of *Geranium latilobum*.

present on stems, petioles, and leaf laminas, whereas it is restricted to the inflorescence in *G. deltoideum*. The large leaves with broad segments are the most striking feature of *G. latilobum*. These leaves have a central segment with a wider base and are more lobed than in similar species, e.g., *G. hernandesii*, *G. deltoideum*, *G. gentryi*, and *G. hystricinum*. Also, the stipules of *G. latilobum* are wider than those of the other species. The leaf lamina is less deeply divided than that of *G. hernandesii* and *G. deltoideum* and is similar to that of *G. gentryi* and *G. hystricinum*. The specimen *Breedlove* 4263 (CAS, from Durango) has leaves with a more hirsute indumentum and with abundant glandular hairs on both surfaces, while in the type collection glandular hairs are scarce (in some leaves no glandular hairs were found) and usually restricted to the base of the leaf (near petiole insertion). On the specimen *Sanders & al.* 22694 (RSA, from Durango) the internodes along the middle portion of the stem bear abundant stout eglandular hairs, some of these prickly-like. *Geranium latilobum* may be distinguished further from *G. gentryi* by its shorter and white petals. The rostrum of the fruit of *G. latilobum* has a narrowed apex shorter than that of *G. gentryi*; the rostrum of *G. hystricinum* abruptly ends in the stigmatic remnants.

**149. *Geranium hystricinum*** H.E. Moore, Contr. Gray Herb. 146: 72, pl. 3 fig. 10, pl. 5 figs. 3, 7. 1943. TYPE LOCALITY: "MEXICO: Guerrero: by stream in thicket in llano, Puerto Rico, Dist. Hinton & al.* 14972 (holotype, GH-00043635!; isotypes, F-0044706F!, NY-00373666!, US-00100916 image!).

*Perennial herbs*, 50-200 cm tall. *Rootstock* and roots unknown. *Stem*

ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.9-2 mm long and patent, glandular hairs 0.5-0.9 mm long. *Basal leaves* unknown, cauline leaves opposite; leaf lamina 2.8-5.3 cm long, 3.3-6.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.71-0.79], polygonal (medium and upper hastate) in outline, base cordate to subtruncate, not coriaceous, with nerves not projected, hirsute, with  $\pm$  patent, eglandular hairs and glandular hairs on both surfaces; segments 3-5, in 1 plane, middle segment rhombic, 7.9-12.9(15.3) mm wide at the base [ratio segment width at the base/middle segment length = 0.28-0.36], 9-16-lobed in distal half [ratio secondary sinus length/middle segment length = 0.07-0.17]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.7-1.6 mm long and patent, glandular hairs 0.3-0.7 mm long; stipules 3.9-7.5 mm long, 1.8-2.5 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1-3.4]; peduncles 21-72 mm long, with patent to retrorse, eglandular hairs 0.2-1.3 mm long and patent, glandular hairs 0.4-0.9 mm long; bracteoles 3.3-4.1 mm long, 0.9-1.5 mm wide, lanceolate, whorled; pedicels 18-37 mm long, with patent to retrorse, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.6-1 mm long. Flowers actinomorphic. *Sepals* 6.4-7.8 mm long, 3.1-4.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.9-1.9 mm long [ratio mucro length/sepal length = 0.12-0.26], with antrorse to patent, eglandular hairs 0.2-1.5 mm long and patent, glandular hairs 0.6-0.9 mm on the abaxial surface, glabrous adaxially. *Petals* 6.1-8.1 mm long, 3-4.8 mm wide, erect-patent,

emarginate (notch 0.5-1.2 mm deep), without claw, white, hairy on the basal 1/2-3/4 of their adaxial surface, ciliate on the basal margin, with hairs 0.7-1.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.2-5.3 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-0.8 mm long; anthers 0.9-1.2 mm long, yellow. *Nectaries* 5, hemispheric, with a tuft of hairs covering all of its surface. *Gynoecium* 4.2-6.5 mm long, yellow. *Fruit* 24.9-26.3 mm long, erect, discharge of seed-ejection type; mericarps 3.3-4.4 mm long, 1.9-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1-2 transverse veins at the apex), without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.6-0.8 mm long and patent, glandular hairs 0.5-1 mm long; rostrum 16.4-18.7 mm long, without a narrowed apex, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and, usually, patent, glandular hairs 0.5-0.7 mm long; stigmatic remnants 2.3-3.1 mm long, with 5 glabrous lobes. *Seeds* 2.4-2.7 mm long, 1.4-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 384.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to August.

*Distribution*. This species is endemic to central Guerrero, in southern Mexico (Fig. 385).

*Habitat*. Stream banks with shrub cover; 1800-2400 m.

*Additional specimens examined*. **MEXICO**. GUERRERO: Balsamar, 11 km SE hacia la Soledad, 17°33'N, 99°44'W, 28 Jan. 1998, *Calónico* 7421 (IEB); Carrizal de Bravo, 15 km SE hacia la Soledad, 17°34'N, 99°47'W, 28 Jan. 1998, *Calónico* 7478 (IEB).

*Discussion*. *Geranium hystricinum* is quite similar to *G. gentryi*. As Moore (1943: 75) stated, both species are

alike in habit, indumentum, and leaf shape. *Geranium hystricinum* has been collected only a few times, and some aspects of the base of the plant remain unknown. The comments about life-span and basal leaves presented above for *G. gentryi* are applicable to *G. hystricinum*. The petals of *G. hystricinum* are short, white, and deeply notched, whereas those of *G.*

*gentryi* are long, purplish, and slightly or not notched. Moreover, in *G. hystricinum* the petals are hairy adaxially with eglandular, long hairs reaching the apex, while in *G. gentryi* the hairs are shorter and restricted to the basal area. The fruit of *G. hystricinum* has a rostrum that ends abruptly in stigmatic remnants; it has a distinct narrowed apex in *G. gentryi*.

**150. *Geranium lilacinum*** R. Knuth, Bull. Misc. Inform. 1937(10): 502. 1937. TYPE LOCALITY: "State of Mexico. Fig. 385. Distribution of *Geranium hystricinum*.

9-13(17)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.12-0.27]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-1.2 mm long and, sometimes, patent, glandular hairs 0.4-0.7 mm long; stipules 4-8.5 mm long, 0.5-1.3 mm wide, lanceolate, free,

papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.2-3.3]; peduncles (27)40-60(83) mm long, with patent to retrorse, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.3-1.2 mm long; bracteoles 2.5-5.8 mm long, 0.4-0.7

mm wide, lanceolate, whorled; pedicels 9.3-18.3 mm long, with patent to retrorse, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.7-1.2 mm long. Flowers actinomorphic. *Sepals* 4.9-6.7 mm long, 2.3-3.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1-1.9 mm long [ratio mucro length/sepal length = 0.16-0.34], with antrorse to patent, eglandular hairs 0.2-0.9 mm long and patent, glandular hairs 0.5-1.2 mm on the abaxial surface, glabrous adaxially. *Petals* (10)11.3-12.9(15) mm long, 5-6.9 mm wide, erect-patent, rounded, without claw, purple, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.1-8 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-0.9 mm long; anthers 0.9-1.5 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 4.5-7.7 mm long, yellow. *Fruit* 24-31 mm long, erect, discharge of seed-ejection type; mericarps 3.4-4 mm long, 1.5-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.7 mm long and patent, glandular hairs 0.7-1.1 mm long; rostrum 16.9-23.5 mm long, with a narrowed apex 2.4-5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.7-1.2 mm long; stigmatic remnants 2.7-3.5 mm long, with 5 glabrous lobes. *Seeds* 2.2-2.5 mm long, 1.1-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 386.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges through central Mexico (Fig. 387).

*Habitat*. Wet ravines and ridges with *Abies* Mill., *Carpinus* L., *Pinus* L., and *Quercus* L. forests; 2000-3000 m.

**Discussion.** *Geranium lilacinum*, an endemic of central Mexico, is quite similar to *G. deltoideum*. Both species share a prostrate to ascending habit with polygonal leaves towards the base, hastate middle and distal leaves, and glandular hairs restricted to the inflorescence. According to labels, *G. lilacinum* reaches a height of 2 m, although herbarium specimens show only small fragments. The petals of *G. lilacinum* have an indumentum of short hairs restricted to the base of the adaxial surface and the basal margin, whereas in *G. deltoideum* such hairs are longer and spread over most of the adaxial surface. Additionally, *G. lilacinum* has erect-patent purplish petals, and *G. deltoideum* has patent and white to pinkish petals. Glandular hairs on the inflorescence, sepals, and fruits are longer in *G. lilacinum* than in *G. deltoideum*, although with some overlap, and nectaries are glabrous in the first and hairy in the second. According to Rzedowski & Rzedowski (1995: 24), both species can be found growing together and flowering at the same time, but they are easy to differentiate by the characters listed.

**151. *Geranium hintonii*** H.E. Moore, Contr. Gray Herb. 146: 80, pl. 1 fig. 5. 1943. TYPE LOCALITY: "MEXICO: Guerrero: open pine and fir forest, Teotepec, Dist. Mina, 3200 m., Nov. 5, 1939, Hinton 14787 (G, type)". TYPE: Mexico. Guerrero, Mina, Teotepec, 17°28'N, 100°03'W, 5 Nov. 1939, *G.B. *Discussion*. *Geranium hintonii* has  
a vertical, thin rootstock giving rise  
to some prostrate to ascending aerial  
stems. These stems root at the nodes  
and have 2-flowered cymules arising  
singly. The indumentum consists of  
thin, eglandular hairs on stems, pet-

Fig. 389. Distribution of *Geranium hintonii*.

ioles, and leaves. The inflorescences also bear abundant glandular hairs, especially on pedicels and sepals. The petals are long, emarginate, and hairy adaxially. These hairs are usually restricted to the basal third of the adaxial surface, although sometimes they reach the center. *Geranium hintonii* shares with *G. monanthum* a similar leaf shape, inflorescence structure, emarginate and hairy petals, and glabrous nectaries; however, *G. monanthum* differs in its 1-flowered cymes, ovate stipules, and a typical indumentum composed of retrorse, appressed, eglandular hairs extending from the stem base to the inflorescence (with some patent, glandular hairs on the stem). Additionally, the apex of stems of *G. monanthum* ends in a bud without leaves, while in *G. hintonii* the stems terminate in a cymule. Both species have well-defined allopatric ranges in the Sierra Madre del Sur, *G. hintonii* in Guerrero and *G. monanthum* in Oaxaca.

**152. *Geranium monanthum*** Small in Underw. & Britton (eds.), N. Amer. Fl. 25(1): 21. 1907. TYPE LOCALITY: "Type collected on the northwest side, near the summit, of Mt. Zempoaltepec, Oaxaca, Mexico, July 9, 1894, E. W. Nelson 659". TYPE: Mexico. Oaxaca, Mt. Zempoaltepec, 17°10'N, 95°59'W, 9 July 1894, E.W. Nelson 659 (holotype, US-00130525 image!).

*Perennial herbs*, 17-27 cm tall. *Rootstock* 1.7-3.2 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.6-1.4 mm long. *Basal leaves* unknown, *cauline leaves* opposite; leaf laminae 1.7-2.7 cm long, 2.1-3.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.82-0.90], polygonal in outline, base

cordate, not coriaceous, with nerves not projected, with scattered,  $\pm$  appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic (with lanceolate lobes), 1.8-5.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.30], 5-8-lobed in distal half [ratio sec-

ondary sinus length/middle segment length = 0.28-0.43]; petioles up to 4 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; stipules 3.9-6.9 mm long, 1.1-3.7 mm wide, ovate, free, papery, brownish red, with eglandular hairs on abaxial surface

and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 2.4-3.6]; peduncles 14-51 mm long, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; bracteoles 3.3-7.3 mm long, 0.7-1.6 mm wide, lanceolate, opposite; pedicels 10.7-20.9 mm long, with retrorse, appressed, eglandular hairs 0.2-0.3 mm long. Flowers actinomorphic. *Sepals* 5.5-8.2 mm long, 2.1-3.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.2-2.1 mm long [ratio mucro length/sepal length = 0.17-0.31], with antrorse to patent, eglandular hairs 0.3-1.1 mm long on the abaxial surface, almost glabrous adaxially. *Petals* (9.9)11.7-14.1 mm long, 6.7-9.2 mm wide, erect-patent, emarginate (notch 0.6-1.9 mm deep), without claw, white to lavender, hairy on the basal 3/4 of their adaxial surface and on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.6-1.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.9-7.5 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.7 mm long; anthers 1.4-1.8 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 6.1-8.9 mm long, yellow. *Fruit* unknown. *Seeds* unknown. *Cotyledons* not studied. Fig. 390.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

Fig. 391. Distribution of *Geranium monanthum*.

*Phenology*. Collected in flower from February to November.

*Distribution*. This species is endemic to central Oaxaca, in southern Mexico (Fig. 391).

*Habitat*. On clay and loam soil, in secondary growth and *Pinus* L.-*Quercus* L. forests; 2400-3400 m.

*Additional specimens examined*. **Mexico**. OAXACA: Zempoaltepetl, top of the mountain, 17°10'N, 95°59'W, 19 Feb. 1937, *Camp* 2624 (GH, MICH, NY, P, RSA); between Yalina and Natividad, 17°15'N, 96°21'W, 4 Nov. 1952, *Oberg* s.n. (CAS); Ixtlán, municipio de Ixtlán, 2 km N of the turnoff to Ixtlán de Juárez on highway 175, 17°20'N, 96°27'W, 5 Mar. 1981, *Martin* 403 (CAS, MO).

*Discussion*. The rootstock of *G. monanthum* is horizontal, relatively long and slim, and has several aerial stems arising from it at intervals. The available specimens do not include a basal leaf (nor dry vestiges) at the base of aerial stems. Broad, brown stipules enclose the base of stems and especially the growing tip. The indumentum of *G. monanthum* is mostly constituted of short, appressed, eglandular hairs; however, at the base of aerial stems there are a few long and thin, glandular hairs. It is noteworthy that petals of *G. monanthum* have long, spreading, eglandular hairs on most of the adaxial surface and some at the base of the abaxial surface. Moore (1943: 56) assigned *G. monanthum* to his series *Bella* with doubts because of its superficial resemblance to *G. potentillifolium*; however, *G. monanthum* most likely is allied with *G. hintonii*.

**The Seemannii Group**—This group is characterized by its trailing and ascending habit, its palmatifid or palmatisect, opposite leaves, and its 2-flowered cymules arranged in monochasial inflorescence. The petals are of small size and hairy on basal margins and on the base of the adaxial surface.

*Perennial herbs*, 10-200 cm tall. *Rootstock* 1.7-9.4 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* trailing and ascending, leafy, sometimes rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.5-2 mm long and, rarely, patent, glandular hairs 0.7-0.8 mm long. *Basal leaves* in a ± deciduous rosette, cauline leaves opposite; leaf laminas 1.9-6.1 cm long, 2.2-7.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.77)0.79-0.88(0.92)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 1.4-10.8 mm wide at the base [ratio segment width at the base/middle segment length = (0.09)0.11-0.25(0.30)], (5)9-20-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.31(0.41)]; petioles up to 25 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-1.8 mm long and, rarely, patent, glandular hairs 0.6-0.8 mm long; stipules 3.3-11.6 mm long, 0.6-2.3 mm wide, linear-lanceolate (sometimes with a short bifid apex), free, papery, brownish red, with eglandular hairs on both surfaces

and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.3)0.8-4.9]; peduncles (9)18-87(111) mm long, with patent to retrorse, eglandular hairs 0.2-1.7 mm long and, usually, patent, glandular hairs 0.3-1.2 mm long; bracteoles 2.2-7.3 mm long, 0.2-1.5 mm wide, linear-lanceolate, whorled; pedicels 2-39.4 mm long, with patent to retrorse, eglandular hairs 0.2-1 mm long and patent, glandular hairs 0.4-1.2 mm long. Flowers actinomorphic. *Sepals* (3.4)4.3-6.4(7.5) mm long, 1.6-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.3)0.7-1.1(1.8) mm long [ratio mucro length/sepal length = 0.06-0.33], with erect-patent, eglandular hairs 0.1-1.2 mm long and patent, glandular hairs 0.4-1.3 mm long on the abaxial surface, glabrous adaxially. *Petals* 3.5-13.9 mm long, 1.6-7.4 mm wide, erect-patent, slightly emarginate (notch 0.3-1.3 mm deep), without claw, purple, rarely white, glabrous on both surfaces or hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.1-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.7-6.5 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.1-0.7 mm long on the abaxial surface and margin; anthers 0.3-1.7 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.2-7.6 mm long, yellow or purple. *Fruit* 15.2-23.5 mm long, erect, discharge of seed-ejection type; mericarps 2.4-3.8 mm long, 1-2 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at the apex), without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-1 mm long and usually, patent, glandular hairs 0.3-1.2 mm long; rostrum 10.1-17.7 mm long, with a narrowed apex (0.5)0.7-2.7(3.8) mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.9 mm long and patent, glandular hairs

0.5-1.3 mm long; stigmatic remnants 1-3.6 mm long, with 5 sometimes hairy lobes. *Seeds* 1.9-2.5 mm long, 1.1-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 52$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from southern U.S.A., through Mexico, Guatemala, El Salvador, Honduras, Nicaragua and Costa Rica to Panama and it is introduced in Ecuador.

*Habitat*. Disturbed areas, stream-sides, meadows, pastures, shrubby slopes, and forests; 50-4100 m.

1. Petals (3.5)4.5-6.4(9.1) mm long; ratio main-sinus length/middle segment length = (0.77)0.79-0.85(0.90).

**153a. subsp. seemannii**

1. Petals 10-12.3(13.9) mm long; ratio main-sinus length/middle segment length = (0.80)0.84-0.88(0.92).

to near summit, 8°49'N, 82°32'W, 24 July 1975, Mori & Bolten 7424 (MEXU).

**Discussion.** *Geranium seemannii*, a weedy and widespread species of Mexico and Central America, is well characterized by its vertical rootstock, trailing or ascending aerial stems (sometimes rooting at the nodes), the usual presence of a glandular indumentum on inflorescences, glabrous nectaries, and short and glabrous petals. Moore (1943: 82) recognized the variability of plants belonging to his series *Vulcanicola*; he stated: "Nearly every character varies inconstantly with little decisive geographic significance", and, specifically in *G. seemannii*, "... there is considerable variation throughout the range of this species but, without a better knowledge of distribution and stability of phases, the description of minor variations would only add to the confusion" (Moore 1943: 87). Yet, he described or accepted as species seven of these variants, most of them in central Mexico. Later authors, who worked in the region, considered this analytical point of view as impracticable (Arreguín 1979: 358; Rzedowski & Rzedowski 1995: 35; Utrera-Barillas 2000: 31) and placed most of the segregate names in synonymy. They agreed that only *G. cruceroense* can be clearly separated from *G. seemannii* by its palmatisect leaves, which is in accordance with my observations. Moore (1943) recognized two species in Central America: *G. guatemalense* and *G. repens*. He compared *G. guatemalense* with *G. seemannii* and pointed out that both species "... are very close in general floral characters, differing chiefly in habit and leaf characters", with *G. guatemalense* less robust and having more deeply divided leaves. Yet, I have found significant variation in habit and leaf-division throughout the range of *G. seemannii* and therefore consider *G. guatemalense* a synonym of *G. seemannii*. Moore's view was accepted by Standley & Steyermark (1946: 371) for Guatemala and

by MacBryde (1968: 202) for Panama. According to these authors, *G. guatemalense* occurs at intermediate elevations, and it is characterized by its less divided leaves, short petals, and fruits with a short rostrum apex; *G. repens* is a species of higher elevations, with deeply dissected leaves, long petals, and fruits with a long rostrum apex. Burger (1991: 20), in his treatment of *Geranium* of Costa Rica, preferred to submerge *G. repens* within *G. guatemalense*, since "... the flowers are remarkably alike and the distinctions of length of the stylar beak in fruit seem insignificant". He continued, "These differences appear to be clinal and may be worthy of subspecific recognition". I agree with Burger (1991: 20), since the cited combination of characters is only found in higher mountains of southern Mexico, Guatemala, Costa Rica, and Panama. In other regions of its range, *G. seemannii* can have deeply divided leaves, a long rostrum apex, or even long petals (but shorter than 10 mm), but I have never observed all these features on the same individual. Populations of *G. seemannii* with the more common array of characteristics have also been sampled in the mountains of Central America and apparently occur at the same localities and elevations as those with aspects of *G. repens*. Thus, some doubts remain about the status of subsp. *repens*, and field work perhaps may lead to an understanding of the variation within populations and the stability of key characters of this taxon. In summary, plants here identified as subsp. *repens* are recognized basically by the long petals. Additionally, this subspecies has the leaves more deeply divided (with narrow lobes, and deeper first and secondary divisions), and longer peduncles, pedicels, sepals, staminal filaments, anthers, rostrum apex, and stigmatic remnants, although with more or less broad overlap. Knuth (1912: 196) used the name *G. mexicanum* for *G. seemannii*. He was followed by later botanists until Moore (1943: 86) clar-

ified the correct application of both names, and rightly noted the original use of *G. mexicanum* for plants with longer pedicels and petals.

Specimens of *G. seemannii* subsp. *seemannii* collected around Quito and Loja (Ecuador) match Mexican plants very well. They occur in disturbed habitats near these cities and are probably introduced weeds. In Ecuador *G. seemannii* subsp. *seemannii* could be confused with *G. killipii*, but it usually has leaves with the middle segments more lobed, shorter petals, shorter peduncles and pedicels, and a shorter rostrum apex than found in *G. killipii*.

*Geranium seemannii* subsp. *repens* may be confused with *G. lilacinum*, which is well characterized by its middle and distal cauline leaves that are hastate in outline and have broader and shallower segments. *Geranium clarum* seems to be a form of subsp. *repens* without glandular hairs from Oaxaca, and the name is here provisionally placed in synonymy. The type is an incomplete specimen (digital image seen). Field work at the type locality may help to clarify the status of this taxon.

---

**154. *Geranium cruceroense*** R. Knuth, Bull. Misc. Inform. 1937(10): 502. 1937, ["cruceroense"]. TYPE LOCALITY: "State of Mexico. District of Temascaltepec: Crucero Agua Blanca, on the llano, 3250 m., Aug. 1933, Hinton 4617 (typus in herb. Kew.), 'flower white'; Crucero, 2880 m., July 1933, Hinton 4188". TYPE: Mexico. Mexico, Temascaltepec, Crucero Agua Blanca, 19°8'N, 99°50'W, 30 Aug. 1933, *G.B. Hinton 4617* (holotype, K-000531442!; isotypes, BM!, FI, GH-00043625!, LL, MO-060432!, NY!, US-00100874 image!).

*Geranium radiatum* Small in Underw. & Britton (eds.), N. Amer. Fl. 25(1): 11. 1907, nom. illeg., non Andrews 1802. TYPE LOCALITY: "Type collected on the Sierra de Pachuca, Hidalgo, Mexico, July 21 and 22, 1901, J. N. Rose & R. Hay 5620". TYPE: Mexico. Hidalgo, Sierra de Pachuca, 20°11'N,

98°42'W, 21-22 July 1901, J.N. Rose & R. Hay 5620 (holotype, NY-00373677!; isotypes, F, US-00100948 image!).

*Perennial herbs*, 16-35(40) cm tall. *Rootstock* 1.3-6.2 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* trailing and ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-4 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 1.4-2.9 cm long, 1.6-4 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 0.3-2.2 mm wide at the base [ratio segment width at the base/middle segment length = (0.04)0.07-0.10(0.12)], 5-12-lobed in distal half [ratio secondary sinus length/middle segment length = 0.26-0.44]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long; stipules 2.6-8.3 mm long, 0.8-1.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.9)1.3-1.9]; peduncles (11)13-23(66) mm long, with patent to retrorse, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.2-0.8 mm long; bracteoles 2.7-5.4 mm long, 0.5-1 mm wide, linear-lanceolate, whorled; pedicels 3.7-10.5 mm long, with patent to retrorse, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* (3.3)4.4-5.1(5.6) mm long, 1.5-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.2)0.2-0.3(0.6) mm long [ratio mucro length/sepal length = 0.05-0.12], with erect-patent, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.4-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.2)5.1-6.4(6.8) mm long,

1.6-3 mm wide, erect-patent, slightly emarginate (notch 0.3-0.7 mm deep), without claw, white, glabrous or ciliate on the basal margin, with hairs 0.1-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.2-3.8 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.1-0.2 mm long on the abaxial surface and mar-

gin; anthers 0.4-0.8 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.5-4 mm long, yellow. *Fruit* 15-19 mm long, erect, discharge of seed-ejection type; mericarps 2.5-3.3 mm long, 1.2-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1 transverse vein at the apex), without basal beak, with a basal callus, without a basal

MICHOACÁN: Santa Clara del Cobre, alrededores de la lagunita de San Gregorio, 19°24'N, 101°32'W, 8 Oct. 1995, *Rzedowski 52786* (MEXU).

*Discussion*. *Geranium cruceroense* shares with *G. seemannii* subsp. *seemannii* a similar habit, short petals with a usually ciliate base and an emarginate apex, glabrous nectaries, and a fruit rostrum with a short narrowed apex. *Geranium cruceroense* is set apart by its palmatisect leaves with distinctive deep and narrow lobes and by a very short sepal mucro. Additionally, the stems and petioles have an indumentum of short, retrorse, appressed, eglandular hairs. The original spelling of the epithet is "*cruceroense*". According to Art. 60.7 of the ICN, the diaeresis may be omitted. I chose to do so for several reasons. IPNI lists "*cruceroense*" in accordance with *Index Kewensis*; the record from the *Gray Card Index* reads "*cruceroense*", an erroneous

substitution for the diaeresis. In some floristic publications the spelling "*cruceroense*" prevails (e.g., Arreguín 1979: 356; Utrera-Barillas 2000: 16), although Rzedowski & Rzedowski (1995: 14) retained the diaeresis. Also, the use of stress marks may be a disadvantage for computer searches.

### Other species from Mexico

**Discussion.** *Geranium alpicola* is easily identified by its distinctive, deeply divided leaves, usually in five segments and each divided into 3-8 narrow, long lobes. The adaxial surface has scattered appressed hairs, and the margins are somewhat recurved. Thus, the abaxial surface is like a channel covered by a dense sericeous indumentum. The characteristic indumentum of antrorse, appressed, eglandular hairs covers the entire plant in variable densities, but is sericeous only on sepals, the abaxial leaf surface, and fruits. In some cases, the nerves stand out from the white sepal surface by their purplish color. Although most of the fruit is sericeous, the narrow apex of the rostrum and the stigmatic remnants are glabrous. As Moore (1943:

21) pointed out, *G. alpicola* is variable in the length of the stem. Some small herbarium specimens have cymules arising only from the rootstock. Specimens with well-developed aerial stems bearing 1-3 pairs of opposite leaves are more common, although in these plants it is not rare to find some cymules arising directly from the rootstock as well. Moore (1943: 21) suggested that this variation is related to environmental conditions and noted some resemblance among *G. alpicola* and stemless species from South America, such as *G. humboldtii* or *G. sibbaldioides*; however, these species differ in their 1-flowered cymules, leaves with few lobes per segment, stipules ending in 1-3 bristles, and shorter fruits without a narrowed apex.

**156. *Geranium madreense*** Rose ex Hanks & Small in Underw. & Britton (eds.), N. Amer. Fl. 25(1): 17. 1907. TYPE LOCALITY: "Type collected near Santa Teresa, Tepic, Mexico, August 10, 1897, J. N. Rose 2161". TYPE: Mexico. Nayarit [Territorio de Tepic], Santa Teresa, 22°28'N, 104°44'W, 10 Aug. 1897, *J.N. Rose* 2161 (lectotype, designated by Moore 1943: 22, US-00100904 image!; isoelectotypes, GH-00043643!, NY-00373671!).

**Perennial herbs**, 25-35 cm tall. **Rootstock** 9-9.2 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long. **Basal leaves** in a persistent rosette, cauline leaves opposite; leaf laminae 3-3.2 cm long, 3-3.3 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular hairs; segments 5, in more than 1 plane, middle segment rhombic (with linear-lanceolate

Fig. 398. Distribution of *Geranium alpicola*.

lobes), ca. 0.7 mm wide at the base [ratio segment width at the base/middle segment length = ca. 0.03], 3(4)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.47-0.57]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; stipules 3.4-5.8 mm long, 0.6-1 mm wide, lanceolate, free, papery, brownish red, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.8-7.2]; peduncles 39-100 mm long, with retrorse to uncinete eglandular hairs 0.1-0.2 mm long and patent, glandular hairs 0.2-0.5 mm long; bracteoles 3.5-4.5 mm long, 0.6-0.8 mm wide, lanceolate, whorled; pedicels 19.5-47 mm long, with retrorse to uncinete eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.2-0.5 mm long. Flowers actinomorphic. *Sepals* 9.3-10 mm long, 2.3-3.2 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.4-1.3 mm long [ratio mucro length/sepal length = 0.05-0.14], with antrorse, appressed, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.2-0.5 mm on the abaxial surface, glabrous adaxially. *Petals* 15.3-16 mm long, 9.3-10 mm wide, erect-patent, rounded, without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 8.9-9.1 mm long, lanceolate, unknown color, with eglandular hairs 0.3-0.4 mm long mostly on the margin; anthers 2-2.2 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 8-9 mm long, unknown color. *Fruit* 36-37 mm long, erect, discharge of seed-ejection type; mericarps 5.4-5.5 mm long, 2.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a

basal prong, brown, with erect-patent, eglandular hairs 0.2-0.4 mm long and, patent, glandular hairs 0.2-0.5 mm long; rostrum 28-29 mm long, with a narrowed apex 4-4.2 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and

patent, glandular hairs 0.2-0.4 mm long; stigmatic remnants 2-3 mm long, with 5 glabrous lobes. *Seeds* unknown. Cotyledons not studied. Fig. 399.

*Pollen*. Ornamentation not studied. *Chromosome number*. Unknown.

Detail showing peduncle indumentum. h. Flower, sepals and petals removed. i. Sepal. j. Petal, adaxial side. k. Staminal filament. l. Fruit. m. Mericarp. (Based on: Rose 2161, GH, NY).

**Phenology.** Collected in flower in August.

**Distribution.** This species is endemic to northern Nayarit, in western Mexico (Fig. 400).

**Habitat.** Unknown; ca. 2000 m.

**Discussion.** *Geranium madrense* is known only from the type, collected in Nayarit, Mexico. It is easily recognized by its deeply dissected leaves with five segments divided in three or four long and narrow lobes. The leaves are sericeous on both surfaces when young, but they soon lose most the indumentum and retain only scattered hairs. The petals are hairy only at the base, mainly adaxially and on the margin. *Geranium madrense* can be easily differentiated from *G. alpicola* by its inflorescence with glandular hairs. Additionally, *G. madrense* has retrorse to uncinata, eglandular hairs on peduncles and pedicels, whereas *G. alpicola* has antrorse, appressed eglandular hairs. Both species share petals with the indumentum restricted to the base and glabrous nectaries. The morphological variability of *G. madrense* is unknown, because only two sheets of the type collection were available to me for study. *Geranium madrense* was recorded from Durango (González Elizondo & al. 1991), but I did not see the voucher (*Pennell 18293*, MEXU).

Fig. 400. Distribution of *Geranium madrense*.

**157. *Geranium charucanum*** Standl., Publ. Field Mus. Nat. Hist., Bot. Ser. 22(1): 32. 1940. TYPE LOCALITY: "Mexico: Sierra Charuco, Río Fuerte, Chihuahua, riparian, September 13, 1935, Howard Scott Gentry 1813 (type in Herb. Field Mus.)". TYPE: Mexico. Chihuahua, Sierra Charuco, Río Fuerte, 27°35'N, 108°44'W, 13 Sep. 1935, H.S. Gentry 1813 (holotype, F-0044700F; isotypes, GH-00043622!, MO-060433!).

*Perennial herbs*, 32-110 cm tall. *Rootstock* 3.3-6 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* unknown, cauline leaves usually opposite; leaf laminae 3.7-10.7 cm long, 5.3-11.6 cm wide, not peltate, usually palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic (with lanceolate lobes), 0.6-1(7.6) mm wide at the base [ratio segment width at the base/middle segment length = 0.01-0.02], 5-10(13)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.10-0.45]; petioles up to 41 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules 4-9.8 mm long, 1-2.9 mm wide, lanceolate, free, papery, brownish red, with scattered, eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.1-7.8]; peduncles 49-131(290) mm long, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; bracteoles 3.2-7 mm long, 0.6-1.3 mm wide, lanceolate, whorled; pedicels 12-70 mm long, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long. Flowers

actinomorphic. *Sepals* 5.5-8.5 mm long, 2.8-4.1 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.6-2.9 mm long [ratio mucro length/sepal length = 0.10-0.38], with antrorse, appressed, eglandular hairs 0.2-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* 13.4-16.3(17.5) mm long, 6.2-12.1 mm wide, erect-patent, rounded or slightly emarginate (notch ca. 0.4 mm deep), without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.2-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.4-7.2 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.9 mm long; anthers 0.9-2.2 mm long, yellow. Nectaries 5, hemispheric, usually glabrous. *Gynoecium* 5.8-7.9 mm long, purple. *Fruit* 21.1-33.6 mm long, erect, discharge of seed-ejection type; mericarps 3.9-4.6 mm long, 1.8-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.8 mm long; rostrum 13.9-23.7 mm long, with a narrowed apex 1.8-4.6 mm long, not twisted, with erect-patent, eglandular hairs 0.4-0.6 mm long; stigmatic remnants 3-3.7 mm long, with 5 glabrous lobes. *Seeds* 2.8-3.3 mm long, 2.1-2.2 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 401.

**Pollen.** Ornamentation not studied.

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from August to September.

**Distribution.** This species ranges from central Chihuahua to northern Sinaloa, in northern Mexico (Fig. 402).

**Habitat.** Meadows and rocky areas in *Cupressus* L., *Pinus* L., and *Quercus* L. forests; 1500-2100 m.

**Additional specimens examined. Mexico.** CHIHUAHUA: pr. Areponapuchic, slopes of Barranca de Urique, 27°30'N, 107°50'W,

20 Aug. 1954, *Knobloch 1322* (MICH); Río Mayo region, Sierra Canelo, 27°42'N, 108°40'W, 27 Aug. 1936, *Gentry 2481* (F, MEXU); Río Mayo region, Loreto, 27°44'N, 108°33'W, 3 Sep. 1936, *Gentry 2576* (MEXU, MO); Río Mayo region, Yepachic, 28°24'N, 108°20'W, 15 Aug. 1987, *Martin & al. s.n.* (MEXU). SINALOA: Ocurahui, Sierra Surotato, 25°55'N, 107°39'W, 10 Sep. 1941, *Gentry 6341* (MICH, MO, NY). SONORA: Cerro Sahuarivo, E of San Bernardo, along stream río Curahui, 27°21'N, 108°40'W, 7 Aug. 1935, *Pennell 19591* (NY); Río Mayo re-

gion, Sahuaribo Waterfall vicinity 2 km N of Sahuaribo on road to Curohui, 27°21'N, 108°40'W, 20 Aug. 1992, *Martin & al. s.n.* (MO, RSA).

**Discussion.** *Geranium charucanum* is a robust species of which the basal parts (i.e., rootstock, basal leaves, etc.), are only imperfectly known. I saw only one specimen with one fragment of rootstock and a few basal leaves

(*Martin & al. s.n.*, MEXU-641544). The middle and distal leaves are palmatisect with narrow and rhombic segments, similar to those of *G. niveum*, *G. alpicola*, and *G. madrese*; however, *G. charucanum* has shorter and wider lobes than the other species. The collection *Gentry 6341* (MICH, NY) includes a detached leaf that is deeply palmatifid, not palmatisect like the cauline leaves, and perhaps is a basal leaf. *Geranium charucanum* usually has opposite leaves, although some specimens have an alternate leaf on the middle part of the stem. The leaves are always opposite in the inflorescence, and the distal ones have fewer segments and lobes, which is similar to the pattern found in *G. niveum*, *G. alpicola*, and *G. madrese*. The indumentum of *G. charucanum* is composed of short, retrorse, appressed eglandular hairs and present on the stems, petioles, and inflorescences, whereas *G. alpicola* has antrorse hairs. Additionally, the leaves of *G. alpicola* are sericeous abaxially, and those of *G. charucanum* have only scattered hairs. In some specimens of *G. charucanum* a sericeous indumentum is present on young petioles and sepals, but these structures soon lose most of this covering and retain only scattered hairs. *Geranium niveum* and *G. madrese* have glandular hairs on the inflorescence, which have not been found in *G. charucanum* and *G. alpicola*.

*Discussion*. *Geranium oxacacanum* has a vertical, short and stout, turnip-shaped rootstock giving rise to an erect aerial stem. Most specimens show a trait unknown in another spe-

cies of *Geranium*: a whorl of 3-6 leaves at the first branch point of the inflorescence. Sometimes a second whorl of leaves is present between the base and the first branch point. Leaves of *G. oaxacanum* are hastate and with three segments, similar to the leaves

of *G. hernandesii*. Few herbarium specimens show basal leaves, since these soon fall. They are pentagonal in outline and have five segments. Petals are usually hairy on 1/4-1/3 of the adaxial surface; rarely, hairs are present only at the base. A glan-

Fig. 404. Distribution of *Geranium oaxacanum*.

Fig. 403. *Geranium oaxacanum*. a, b. Habit. c. Leaf, adaxial side. d. Stipules. e. Bracteoles. f. Flower, sepals and petals removed. g. Sepal. h. Petal, adaxial side. i. Stamen. j. Fruit. k. Mericarp. l. Seed. (Based on: a, b, d, e, Pringle 4866, K; c, Liebmann 14905, C; f-i, MacDougall s.n., 14 Oct. 1967, NY; j-l, Conzatti 711, GH).

dular indumentum is present on the inflorescence of most specimens, but in some rare individuals peduncles, pedicels, and sepals lack this type of hairs. No specimens showed both of these exceptional characters. *Geranium oaxacanum* may be mistaken for *G. hernandesii*, especially given the similar leaf shape; however, *G. oaxacanum* has a dichasial inflorescence, shorter peduncles (with some overlap), and usually a glandular indumentum on the inflorescence. Both species share a long sepal mucro, but the sepals of *G. oaxacanum* are shorter than those of *G. hernandesii*. Additionally, leaves of *G. oaxacanum* are whorled at the first branch point. *Geranium oaxacanum* shares with *G. latum* a dichasial inflorescence and adaxially hairy petals, but *G. latum* has nectaries with a tuft of hairs covering its entire surface (not glabrous as in *G. oaxacanum*) and alternate cauline leaves.

**Discussion.** *Geranium trolliifolium* is a robust plant with a very thick, vertical rootstock that is not napiform (at least on the specimens examined). The indumentum of this species is composed of long and usually patent, soft, eglandular hairs on stems, petioles, and inflorescences. Glandular hairs are always present on the inflorescence and often on the basal part of the stem, but more rarely on the petioles. Bracteoles sometimes terminate in a bundle of bristles. Eglandular hairs of staminal filaments are noticeably long and give a characteristic pectinate aspect to these filaments. Glandular hairs of mericarps are usually concentrated towards the apex. In *G. trolliifolium* the rosette leaves are not as deeply divided as those of the stem. In most specimens, the stem bears one alternate leaf, and pairs of opposite leaves are found at the nodes of the inflorescence, although in some cases the stem is naked up to the first branch point of the inflorescence. The inflorescence is usually dichasial with 2-6-flowered cymes and sometimes umbel-like, when the pedicels are reduced or absent. In some specimens an axillary

Fig. 405. *Geranium trolliifolium*. a. Habit. b, c. Leaves. d. Stipules. e. Bracteoles. f. Flower, sepals and petals removed. g. Sepal. h. Petal, abaxial side. i. Petal, adaxial side. j. Stamen. k. Fruit. l. Mericarp. m. Seed. (Based on: a, f-j, *Johnson* 2697, MEXU; c, k-m, *Bye* 1548, MEXU; b, d, e, *Pennell* 18293, GH).

Fig. 406. Distribution of *Geranium trolliifolium*.

cymule grows below the main portion of the inflorescence; this complex arrangement gives the inflorescence a corymbose aspect.

According to Moore (1943: 17), *G. trolliifolium* is allied with *G. oreganum* or *G. viscosissimum* because of its robust habit, simple rootstocks, and compact inflorescences. Yet, these species have opposite leaves, hairy nectaries, and usually solitary cymules (and *G. viscosissimum* also has adaxially hairy petals). If leaf and inflorescence arrangement (and nectary indumentum) are taken into consideration, then *G. trolliifolium* is more similar to *G. sylvaticum* or *G. erianthum*. On the other hand, *G. mexicanum* and *G. trolliifolium* share a stem bearing an alternate leaf and glabrous nectaries. In both species cymules may be multiflowered, but in *G. mexicanum* the peduncles are noticeable longer. *Geranium trolliifolium* shares with *G. crenatifolium* long, soft, patent eglandular hairs on the inflorescence and stem. The affinities of *G. trolliifolium* remain uncertain.

#### 160. *Geranium campanulatum*

Paray, Bol. Soc. Bot. México 16: 22, 23 fig. 2. 1954. TYPE LOCALITY: "Tipo en el Herb. Nac. del Inst. Biol. Méx., ex herbario Paray, Núm. 609, colectado en claros de bosques de pino y encino, de formación volcánica en los "Llanos de la Garza", atrás o sea al norte del pueblo y peña llamada Silleta de Xilitla San Luis Potosí. Crece en un área muy reducida como de 2 Kms. de largo y ancho, entre dos sierras, una llamada de la Silleta de Xilitla y la otra, sierra de San Juan, como a 20 Kms. al norte del pueblo de Xilitla S. Luis Potosí. Altitud sobre el nivel del mar, unos 1,500 m. Prefiere los lugares abiertos, asoleados y terrenos volcánicos. Florece en los meses de Febrero y Abril. La especie fue colectada el 25 de Marzo, cuando estaba en plena floración". TYPE: Mexico. San Luis Potosí, Silleta de Xilitla, Llanos de la Garza, 21°30'N, 99°05'W,

25 Mar. 1953, L. Paray 609 (holotype, ENCB-003240 image!; isotype, MEXU-00015267 image!).

*Perennial herbs*, 40-80 cm tall. *Rootstock* 3.1-7.3 mm in diameter, unknown roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.5-1.4 mm long and patent, glandular hairs 0.4-0.5 mm long. *Basal leaves* unknown, cauline leaves opposite; leaf lamina 5.5-10.5 cm long, 6-13 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.74-0.85], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose on both surfaces, with appressed, eglandular hairs; segments 5, in 1 plane, middle segment rhombic, 10-19.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.25-0.28], 25-29-lobed in distal half [ratio secondary sinus length/middle segment length = 0.17-0.19]; petioles up to 25 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.6-1.3 mm long and, sometimes, patent, glandular hairs 0.2-0.5 mm long; stipules 10-17 mm long, 2.9-5.3 mm wide, broadly lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2-3]; peduncles 33-41(100) mm long, with patent, eglandular hairs 0.3-1.8 mm long and patent, glandular hairs 0.4-0.8 mm long; bracteoles 5.7-8.3 mm long, 1.1-1.4 mm wide, lanceolate, whorled; pedicels 10-14(24) mm long, with patent, eglandular hairs 0.3-1.2 mm long and patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* 10.6-12.3(15.2) mm long, 4.2-5.6 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 3-4.2 mm long [ratio mucro length/sepal length = 0.26-0.33], with  $\pm$  patent, eglandular hairs 0.3-1.4 mm long and

patent, glandular hairs 0.4-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* 19-26(35) mm long, 9.1-14 mm wide, erect-patent, rounded, without claw, purple, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.4-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 16-24(30) mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.9-1.8 mm long; anthers 2.5-2.9 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 11-22 mm long, yellow. *Fruit* 40-45 mm long, erect, discharge of seed-ejection type; mericarps 4-4.3 mm long, 1.7-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.9 mm long and patent, glandular hairs 0.5-0.7 mm long; rostrum 33.7-37.1 mm long, with a narrowed apex 15-18.3 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.6 mm long and patent, glandular hairs 0.3-0.5 mm long; stigmatic remnants 2.6-3.3 mm long, with 5 glabrous lobes. *Seeds* 3.9-5 mm long, 1.1-1.2 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 407.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to April.

*Distribution*. This species is endemic to Querétaro and San Luis Potosí, in central Mexico (Fig. 408).

*Habitat*. Rocky open places among patches of *Cupressus* L., *Pinus* L., and *Quercus* L.; 1500-2300 m.

*Additional specimens examined*. **MEXICO**. QUERÉTARO: Jalpan, Llano de las Avispas, 21°11'N, 99°22'W, 4 Apr. 1991, Díaz & Caranza 6568 (IEB, MICH, MO).

*Discussion*. *Geranium campanulatum*, a rarely collected endemic of central Mexico, is well characterized by its long petals. According to Paray

(1954: 24) and Rzedowski & Rzedowski (1995: 14), the petals vary from 25 to 35 mm long, although in the specimens examined they are a little shorter. Paray (1954) indicated that the corolla is bell-shaped, which is difficult to discern on dry specimens. *Geranium campanulatum* also has long sepals with a long mucro, long staminal filaments, and fruits with the rostrum

terminating in a noticeably long narrowed apex. Glandular hairs are restricted to the inflorescence and distal parts of the stem, while eglandular hairs are found on the entire plant. It is noteworthy that eglandular hairs on the stem and petioles are long and soft, resembling those of *G. trolliifolium*. The underground parts of *G. campanulatum* are unknown. On the avail-

Fig. 408. Distribution of *Geranium campanulatum*.

able specimens the basal part of the stem is covered by old stipules and petiole remnants. The cauline leaves are all opposite, unlike in *G. trolliifolium*, which usually has some alternate leaves. The inflorescence appears to be dichasial, with isolated 2-flowered cymules, not multiflowered cymules in umbel-like aggregates, as in *G. trolliifolium*. The affinity of *G. campanulatum* is difficult to ascertain without more complete material; it resembles *G. trolliifolium* in some aspects, such as the indumentum and robust habit.

**161. *Geranium mooreanum*** Aedo, Acta Bot. Mexicana 95: 39, fig. 1. 2011. TYPE LOCALITY: "México. Jalisco. Sierra de Manantlán, La Cumbre, 19°35'N, 104°08'W, 20-III-1965, McVaugh 23134 (holótipo, MICH!)". TYPE: Mexico. Jalisco, Sierra de Manantlán, La Cumbre, 19°35'N, 104°08'W, 20 Mar. 1965, R. McVaugh 23134 (holotype, MICH!).

*Perennial herbs*, 36-94 cm tall. *Rootstock* 7-8 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with ± patent, eglandular hairs 1.5-2.8 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf

type; mericarps 4-5.6 mm long, 2.4-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.9-1.2 mm long and patent, glandular hairs 0.7-0.9 mm long on the apex; rostrum 27.3-32.3 mm long, with a narrowed apex 6.8-10 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.7-1.1 mm long; stigmatic remnants 2.8-3.7 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.1 mm long, 1.6-2.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 409.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to November.

*Distribution*. This species is endemic to southern Jalisco, in western Mexico (Fig. 410).

*Habitat*. Steep slopes in *Abies* Mill., *Pinus* L., and *Quercus* L. forests; 2250-3000 m.

*Additional specimens examined*. **Mexico**. JALISCO: Sierra de Manantlán, 27-36 km SE of Autlán, about 3.6 km from Aseradero San Miguel Uno, SW of the divide toward Manzanillo, 19°31'N, 104°13'W, 4 Nov. 1952, *McVaugh 13898* (MICH); Sierra de Manantlán, W of El Guisar, 19°33'N, 104°8'W, 30 Jan. 1970, *Boutin & Kimnach 2999* (CAS, MEXU); along lumber road, 0.3 km E of Cerro La Cumbre-Rincón de Manantlán, at crossing of first small stream, N end of Sierra de Manantlán Central, 17.7 km S of El Chante, 19°33'N, 104°13'W, 6 Jan. 1980, *Sorensen & al. 7882* (MEXU).

*Discussion*. *Geranium mooreanum* resembles *G. campanulatum* in general appearance, inflorescence structure and size, and petal indumentum. Both share a robust habit, glandular indumentum restricted to the inflorescence, and glabrous nectaries. The petals of *G. campanulatum* are longer than those of *G. mooreanum*, although with some overlap. Additionally, the sepal mucro, staminal

filaments, and the narrowed apex of the rostrum are longer in *G. mooreanum*. The fruit of *G. mooreanum* is reflexed when mature, whereas it is erect in *G. campanulatum*. In some specimens *G. mooreanum* the cauline leaves may have three segments and are subhastate in outline, as in *G. lilacinum*, but the leaves are longer and have more lobes per segment. Additionally, *G. mooreanum* can be clearly differentiated from *G. lilacinum* by its longer sepal mucro, petals, staminal filaments, anthers, and narrowed apex of the rostrum. It is endemic to the Sierra de Manantlán, about 500 km west of the localities recorded for *G. campanulatum*. In this region of southern Jalisco *G. deltoideum* and *G. latilobum* also occur, both with shorter adaxially hairy petals, as does *G. seemannii* subsp. *seemannii*, with very short and almost glabrous petals.

---

**162. *Geranium unguiculatum*** H.E. Moore, Contr. Gray Herb. 146: 24, pl. 2 fig. 5, pl. 4 figs. 2, 7. 1943. TYPE LOCALITY: "MEXICO: Guerrero: steep, rocky slopes in oak forest, Yesceros-Cruz Pacifica, Dist. Mina, 2550 m., Nov. 26, 1939, Hinton 14906 (G, Type)". TYPE: Mexico. *Perennial herbs*, 70-150 cm tall. *Rootstock* and roots unknown. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.3-0.5 mm long. *Basal leaves* unknown, cauline leaves opposite; leaf laminae 7.6-11.2 cm long, 9.3-11.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.76-0.84], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 9.4-19.3

mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.24], 8-17-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.19]; petioles up to 26 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.3-0.6 mm long; stipules 3.2-7.5 mm long, 1.9-4.1 mm wide, broadly lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 3.6-8]; peduncles 16-23(31) mm long, with patent, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.2-0.9 mm long; bracteoles 1.6-3.8 mm long, 0.5-1.4 mm wide, lanceolate, whorled; pedicels 13.2-21.5 mm long, with patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.3-0.8 mm long. Flowers actinomorphic. *Sepals* 3.5-5.3 mm long, 1.6-2.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.9(1.1) mm long [ratio mucro length/sepal length = 0.13-0.29], with antrorse to patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.2-0.8 mm long on the abaxial surface, glabrous adaxially. *Petals* 18-22(26.2) mm long, 4.4-9.9 mm wide, erect-patent, rounded, with claw 6.1-11.1 mm long, pink, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.3-5.4 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.3 mm long; anthers 0.5-0.9 mm long, unknown color. Nectaries 5, hemispheric, dorsally hairy. *Gynoecium* 4.3-6.5 mm long, purple. *Fruit* 25.5-27.2 mm long, erect, discharge of seed-ejection type; mericarps 3.5-3.7 mm long, 1.9-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-

0.6 mm long, and patent, glandular hairs 0.6-1.1 mm long; rostrum 17.1-21 mm long, with a narrowed apex 1.7-2.7 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.6-1 mm long; stigmatic remnants 1.9-4.3 mm long, with 5 glabrous lobes. *Seeds*

2.5-2.6 mm long, 1.7-1.8 mm wide, reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 411.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from October to November.

*Distribution*. This species is endemic to western Guerrero, in southwestern Mexico (Fig. 412).

*Habitat*. Steep rocky slopes, cliffs, and *Abies* Mill., *Pinus* L., and *Quercus* L. forests; 1900-3200 m.

*Additional specimens examined*. **Mexico**. GUERRERO: Mina, Fresnos-Cuesta, 18°12'N, 101°17'W, 21 Oct. 1936, *Hinton* 9736 (F, MEXU, MICH, MO, NY, RSA, P).

*Discussion*. *Geranium unguiculatum* is a robust species to 1.5 m tall, according to herbarium labels. Neither of the two collections examined included a rootstock, roots, basal leaves, and basal parts of the stem. The middle and distal leaves are palmatifid and opposite. The indumentum of this species is composed of short and  $\pm$  appressed eglandular hairs on stem, petioles, and leaf surfaces. The inflorescence has also glandular hairs on peduncles, pedicels, the sepal base, and in the fruits on the apex of mericarps and on the rostrum. The inflorescence has a general dichasial structure and some divaricate branches. The leaves are abruptly reduced in size from the second node of the inflorescence towards the apex. The nectaries are completely covered with short white hairs. Among the most distinctive features of *G. unguiculatum* are the long petals with a very long claw (6.1-11.1 mm). As Moore (1943: 25) pointed out, the affinity of *G. unguiculatum* to other species is unknown.

*Discussion*. *Geranium durangense* is easily identified by its glabrous and deep purplish petals, glabrous nectaries, and staminal filaments bearing short hairs only on the margin. The underground part of *G. durangense* is not well known. The small fragments available in herbaria suggest that the species has a vertical rootstock. The inflorescence shows a monochasial

pattern, although towards the apex it ends in some dichasial branches. Moore (1963: 95) described this species as having glandular hairs. In fact, *G. durangense* has minute (less than 0.1 mm long) sessile glands on the inflorescence and leaves. This type of gland is usually omitted in descrip-

tions, because they are found in many species of *Geranium* (although not in the same density). *Geranium durangense* does have an unusual eglandular hairs; they are short, stout, and curved. According to Moore (1963: 95) *G. durangense* is quite similar to *G. latum*. Both species share alternate

Fig. 414. Distribution of *Geranium durangense*.

J. L. Castillejo, 2009

Fig. 413. *Geranium durangense*. a. Habit. b. Detail showing peduncle indumentum. c. Stipules. d. Bracteoles. e. Flower, sepals and petals removed. f. Sepal. g. Petal, adaxial side. h. Stamen. i. Fruit. j. Mericarp. k. Seed. (Based on: a-h, Hernández 7503, MEXU; i-k, Breedlove 44135, MEXU).

leaves on the basal part of the stem; however, *G. latum* has adaxially hairy petals, hairy nectaries, staminal filaments with long hairs, and dichasially branched inflorescences. As Moore (1963: 95) pointed out, *G. durangense* may be related to *G. mexicanum*, a species with glabrous nectaries, short hairs on staminal filaments, and petals hairy only at the base. *Geranium mexicanum* has opposite leaves, long peduncles, cymes 2-4-flowered, and a dichasial inflorescence with glandular hairs.

The collection Pringle 10022 was distributed in the set of exsiccatae "Plantae Mexicanae 1905" with a printed label bearing the name "*Geranium durangensis* Rose", a name that was never published. Moore (1943: 34) correctly identified this Pringle collection as *G. wislizeni*, but did not refer to the unpublished name when he (Moore 1963: 95) proposed his new species *Geranium durangense*.

**The Sibbaldioides Group**—This group is characterized by its scapiform, cushion-like habit, its not turnip-shaped rootstock, its eglandular indumentum, and its 1-flowered cymes arising directly from the rootstock, usually lacking pedicels. The leaves are usually palmatifid, sometimes palmatisect or digitate and in *G. azorelloides* entire with tridentate apex. The petals are

usually of small size and without claw. The first fourteen species may suite a subgroup characterized by its leaves usually glabrescent and with stipules ending in 1-3 bristles.

**164. *Geranium azorelloides*** Sandwith, Bull. Misc. Inform. 1929: 121. 1929. *Geranium guanacosense* R. Knuth, Repert. Spec. Nov. Regni Veg. 40: 219. 1936, nom. illeg. TYPE LOCALITY: "Colombia. Fig. 416. Distribution of *Geranium azurelloides*.

long, lanceolate, yellow, glabrous, or with few eglandular hairs 0.1-0.2 mm long on the margin; anthers ca. 0.7 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* ca. 4 mm long, purple. *Fruit* 10-10.5 mm long, erect, discharge of seed-ejection type; mericarps 1.7-2 mm long, 1.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long on the surface and eglandular hairs 0.5-0.8 mm long on the margin; rostrum 6.5-7 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.2 mm long; stigmatic remnants ca. 1.5 mm long, with 5 glabrous lobes. *Seeds* ca. 1.5 mm long, 1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 415.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to October.

*Distribution*. This species ranges from southwestern Colombia to southern Ecuador (Fig. 416).

*Habitat*. Lake shores, wet or boggy areas on paramo with *Espeletia Mutis* ex Bonpl.; 3000-3450 m.

*Additional specimens examined*. **Colombia**. CAUCA: Macizo Colombiano, Páramo

*Discussion*. *Geranium azurelloides* is a species with a striking leaf lamina, obtriangular in outline and with three shallowly incised segments at the apex. The only other species of *Geranium* with such a leaf lamina are *G. jahnii* (Venezuela) and some representatives of sect. *Neurophyllodes* (endemic to Hawaii); however, in these the petiole is articulated at the lamina or at the stipules, whereas *G. azurelloides* lacks such articulation. *Geranium azurelloides* is stemless; it has bristles at the apex of the stipules and sepals, and has vegetative stems, like some Andean species. *Geranium azurelloides* usually has a glabrous leaf lamina, but some specimens have patent cilia on the margin (*Beck* 13065, (LPB); *Cuatrecasas & Willard* 26343, COL). In most of the specimens examined, the segments of the leaf laminae are entire at the apex, but occasionally these segments have 1-2 lateral teeth (e.g., *Barclay & Juajibioy* 5983, MO).

**165. *Geranium sibbaldioides* Benth.**, Pl. Hartw. 2: 166. 1845. TYPE LOCALITY: "Hacienda de Antisana". TYPE: Ecuador. Antisana, 0°30'S, 70°10'W, 4 Feb. 1826, *K. Hartweg* 126 (lectotype, designated by Aedo & al. 2002: 273, K!).

*Perennial herbs*, 2-28 cm tall. *Root-stock* 0.8-7.2 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.4-1.4 cm long, 0.7-1.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.92], polygonal in outline, base cordate, not coriaceous, with nerves not projected, glabrous or pilose on both surfaces, with antrorse, eglandular cilia 0.1-0.2 mm long on the margin, each segment ending in 1-3 bristles 0.2-0.7 mm long; segments 5, in 1 plane, middle segment lanceolate to obtriangular, 0.5-1.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.11-0.24], 1-3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.19-0.30]; petioles up to 5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, usually appressed, eglandular hairs 0.1-0.7 mm long; stipules 4.9-12 mm long, 0.6-1.7 mm wide, lanceolate (with a setaceous apex 1.5-3.1 mm long), free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.1-0.8 mm long). *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.5-1.8]; peduncles 6-27 mm long, with patent or retrorse, appressed, eglandular hairs 0.2-0.5 mm long; bracteoles absent or 3.5-9.7 mm long, 0.8-2.6 mm wide, linear-lanceolate, opposite; pedicels absent or 4-37.9 mm long, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long. Flowers actinomorphic. *Sepals* 4.2-8 mm long, 1.2-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-1.2

mm long [ratio mucro length/sepal length = 0.07-0.23], with erect-patent, eglandular hairs 0.1-1 mm long on the abaxial surface and margin, glabrous adaxially, ending in 1-4 bristles 0.2-0.7 mm long. *Petals* 5-13.2 mm long, 2.2-5.1 mm wide, erect-patent, rounded, without claw, white to pink, glabrous or hairy on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.7-4.1 mm long, lanceolate, white, glabrous, or with few eglandular hairs 0.1-0.3 mm long on the abaxial surface and margin; anthers 0.5-0.9 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.5-4.1 mm long, yellow. *Fruit* 7.1-11.6 mm long, usually erect, discharge of seed-ejection type; mericarps 1.6-3.1 mm long, 0.7-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal callus, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.5 mm long; rostrum 4.1-7.5 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.5 mm long; stigmatic remnants 0.6-1.8 mm long, with 5 glabrous lobes. *Seeds* 1.1-2.2 mm long, 0.6-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from western Venezuela to western Bolivia.

*Habitat*. Wet puna, grassy paramo and edge of forests; 1900-5000 m.

1. Leaves with eglandular hairs on both surfaces, sometimes only adaxially.

**165c. subsp. *elongatum***

1. Leaves glabrous on both surfaces.

2. Leaves with middle segment broadly lanceolate, 1(2)-lobed at the apex.

*Discussion.* *Geranium sibbaldioides* is extremely variable in indumentum and leaf shape throughout its range, from western Venezuela to northern Bolivia. The type material was collected in Ecuador by Hartweg. This lectotype and most specimens of *G. sibbaldioides* from southern Colombia and Ecuador have leaves with five entire segments, glabrous on both surfaces (with antrorse cilia on the margin); the petioles usually have retrorse, appressed hairs, and the sepals are almost glabrous (with few hairs towards the base). Some specimens sharing these characters have also been collected in northern Peru. Specimens from western Venezuela and northern and central Colombia (and rarely northern Ecuador) usually have the leaf laminae hairy on one or both surfaces and the sepals more or less hairy, the leaf segments are not always entire (often the middle segment is entire, and the lateral ones are 2-3-lobed; rarely the middle segment may be 3-lobed and obtriangular), and sometimes the petioles have patent hairs. Other specimens from southern Ecuador, Peru, and northern Bolivia show a different combination of features: they have glabrous leaves (with antrorse cilia on the margin) with obtriangular 3-lobed segments and almost glabrous sepals. These combinations of characters are correlated with different geographi-

cal ranges, and thus three subspecies are recognized; however, the character suites are not always constant, and a few specimens are difficult to assign to a particular subspecies.

*Geranium igualatense* was based on *Rimbach 426* (B), which was destroyed during the Second World War; no duplicates of this collection were found. Jørgensen & León (1999: 492) considered it conspecific with *G. sibbaldioides*, an opinion here confirmed after examining the original description (Knuth 1930b: 88).

A collection of subsp. *beckianum* (*Barbour 3423*, F, MO) from Peru shows rather more divided leaves than usual but otherwise falls within the circumscription of the subspecies.

*Geranium cucullatum* var. *elongatum* was described by Weddell (1861) as a taxon with hairy leaves; however, the original material cited by him is heterogeneous, covering all the variability of *G. sibbaldioides*: a) glabrous-leaved specimens from Ecuador agree with *G. sibbaldioides* subsp. *sibbaldioides* (*Jameson 496*, E!, P!), b) glabrous-leaved specimens from Peru (i.e., *Lechler 2518*, HAL!, P!, W!) agree with *G. sibbaldioides* subsp. *beckianum*, and c) a hairy-leaved specimen from Colombia (*Goudot s.n.*, P!), the lectotype for *G. cucullatum* var. *elongatum* (Aedo & al. 2002), chosen in agreement with the protologue and Knuth's (1912) monograph. Consequently, the correct name for specimens from western Venezuela and Colombia is *G. sibbaldioides* subsp. *elongatum*. A specimen of subsp. *elongatum*, *Rangel & al. 1582* (COL), with exceptionally long petals (13 mm) was collected in Colombia (Boyacá, Sierra Nevada del Cocuy). It can be distinguished from *G. paludosum* (a similar species with long petals) by its leaves with lanceolate, entire segments, which are hairy on both surfaces.

Ecuador, Prov. Loja, Parque Nacional Podocarpus, Cerro Toledo, montane forest and páramo (79°07'W, 04°23'S), alt. 2500-3400 m, 30 Oct 1989 (AAU holotype)". TYPE: Ecuador. Loja, Parque Nacional Podocarpus, Cerro Toledo, 4°73'N, 79°07'W, 30 Oct. 1989, *J.E. Madsen 86287* (holotype, AAU!; isotypes, QCA!, LOJA!).

*Perennial shrubby*, 4-30 cm tall. *Rootstock* 1.6-4.7 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, with short vegetative stems, glabrous, densely clothed with imbricate persistent stipules and petioles. *Basal leaves* deciduous, cauline leaves alternate; leaf laminae 0.5-1.4 cm long, 0.9-1.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.74-0.91], polygonal in outline, base cordate, not coriaceous, with nerves not projected, usually glabrous on both surfaces, with antrorse, eglandular cilia 0.1-0.2 mm long on the margin, each segment ending in 1-3 bristles 0.2-0.6 mm long; segments 5, in 1 plane, middle segment obtriangular (with lanceolate lobes), 0.5-1.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.07-0.15], (1)3(4)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.13-0.39]; petioles up to 6 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long; stipules 3.8-14.2 mm long, 0.6-2.3 mm wide, lanceolate (with a setaceous apex 1.7-4.3 mm long), free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-2 bristles 0.2-0.5 mm long). Cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.5)1.1-1.8]; peduncles (2.1)3.1-7.9(9.8) mm long, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; bracteoles 5.1-12.3 mm long, 0.7-2.6 mm wide, linear-lanceolate, opposite; pedicels (4.1)5.9-

13.7(20.5) mm long, with retrorse, appressed, eglandular hairs 0.2-0.3 mm long. Flowers actinomorphic. *Sepals* (4.8)5.4-6.3(7.4) mm long, 1.1-2.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.6)0.8-1.2(1.3) mm long [ratio mucro length/sepal length = 0.10-0.22], with scattered, erect-patent, eglandular hairs 0.1-0.4 mm long on margin on the abaxial surface, glabrous adaxially, ending in 1-2 bristles 0.3-0.6 mm long. *Petals* (7.5)8.5-10.6(11) mm long, 1.4-4.7 mm wide, erect-patent, rounded or slightly emarginate (notch 0.3-0.7 mm deep), without claw, purple, glabrous on both surfaces, sometimes ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.4-3.9 mm long, lanceolate, white, glabrous, or with few eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers 0.6-0.8 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.9-4.2 mm long, pink. *Fruit* 9.4-13.8 mm long, reflexed, discharge of seed-ejection type; mericarps 2-3.4 mm long, 1-1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse, ± appressed, eglandular hairs 0.1-0.3 mm long; rostrum 5.4-8.8 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.5-1.4 mm long, with 5 glabrous lobes. *Seeds* 1.7-2.1 mm long, 0.9-1.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 422, 423.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from southern Ecuador to northern Peru (Fig. 424).

*Habitat*. Wet or rocky slopes among pockets of dwarf shrubs of *Puya* Molina and *Chusquea* Kunth, and edge of montane forests; 3000-3700 m.

**Discussion.** *Geranium loxense* is a dwarf shrub with an erect main stem (usually hidden by mosses) that is branched towards the middle. The branches and usually the main stem are covered by old stipules. *Geranium loxense* is also well characterized by its purplish petals and reflexed fruits.

Herbarium specimens of *G. loxense* can be confused with *G. sibbaldioides* subsp. *beckianum*, which is a prostrate herb that usually forms a lax cushion; the short vegetative stems are also covered by old stipules. *Geranium sibbaldioides* subsp. *beckianum* usually has white flowers and erect fruits. *Geranium loxense* also differs in some quantitative characters but with some overlap: stipules with a longer setaceous apex, shorter pedicels, and longer sepal mucros, petals, and seeds. It is noteworthy that the two taxa are sympatric, but no intermediate forms have been recorded.

The leaves of *G. loxense* are usually glabrous, except on the margin. In some specimens from the Cerro Toledo (Loja) the leaves bear hairs on the nerves or only abaxially; yet, the leaves of the holotype and other collections from the same area are glabrous. The middle segment usually has three lobes, although leaves with 1-2(4) lobes are occasionally found. *Geranium loxense* was overlooked in Aedo & al. (2002), and some specimens listed were misidentified as *G. sibbaldioides* subsp. *beckianum*.

**167. *Geranium alonsoi*** Aedo, J. Torrey Bot. Soc. 134: 534, 536 fig. 1. 2007. TYPE LOCALITY: "Colombia. Cundinamarca, Villapinzón, de Villapinzón a Umbita, 21 May 1998, Fernández Alonso et al. 15573 (holotype, MA-641407; isotypes, COL! HUA!)". TYPE: Colombia. Cundinamarca, Villapinzón, de Villapinzón a Umbita, 5°13'N, 73°31'W, 21 May 1998, *J.L. Fernández Alonso & al.* 15573 (holotype, MA-641407!; isotypes, COL!, HUA!).

*Perennial herbs*, 20-69 cm tall. *Rootstock* 0.9-2.7 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, with vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.9-2.1 cm long, 1.3-2.3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.80-0.94], polygonal in outline, base cordate, not coriaceous, with nerves not projected, glabrous on both surfaces (sometimes ± hairy on abaxial surface), with antrorse, eglandular cilia 0.1-0.2 mm long on the

margin, each segment ending in 1-3 bristles 0.3-0.8 mm long; segments 5, in 1 plane, middle segment lanceolate, sometimes obtriangular (with lanceolate lobes), 0.7-1.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.13], 1(3)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.46-0.58]; petioles up to 2.7 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; stipules 7.5-11.7 mm long, 1.1-2.5 mm wide, lanceolate (with a setaceous apex 2.8-4.3 mm long), free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.4-0.8 mm long). *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = (1.9)2.6-4.2]; peduncles 11-34.9 mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long; bracteoles 5-9.2 mm long, 0.7-1.2 mm wide, linear-lanceolate, opposite; pedicels 21-80 mm long, with retrorse, appressed, eglandular hairs 0.1-0.4 mm long. Flowers actinomorphic. *Sepals* 5-8.3 mm long, 1.9-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-1.2 mm long [ratio mucro length/sepal length = 0.07-0.17], with scattered, erect-patent, eglandular hairs 0.4-1.2 mm long on base of abaxial surface and margin, minutely hairy adaxially, ending in 1-3 bristles 0.4-0.8 mm long. *Petals* 7.6-14.1 mm long, 3.4-7.3 mm wide, erect-patent, rounded, without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.8-4 mm long, lanceolate, yellow, glabrous, or with few eglandular hairs 0.2-0.4 mm long on the abaxial surface and margin; anthers 0.8-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.8-6.1 mm long, yellow. *Fruit* 10.6-14.8 mm long, erect, discharge of seed-ejection type; mericarps 2.2-3.3 mm long, 1.2-1.7

mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.3 mm long; rostrum 6.4-9.4 mm long, without a narrowed

apex, not twisted, with erect-patent, eglandular hairs 0.2-0.3 mm long; stigmatic remnants 1.2-2.1 mm long, with 5 glabrous lobes. *Seeds* 1.5-2 mm long, 0.9-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 425.

*Discussion.* *Geranium alonsoi* is an endemic of central Colombia. Among the species of *Geranium* that grow in the Colombian paramos, it resembles most closely *G. sibbaldioides* subsp. *elongatum*, from which it is easily differentiated by its longer cymules, which exceed adjacent leaves. Cymules of *G. alonsoi* have a well-developed peduncle, a pair of bracteoles, and a pedicel, whereas in *G. sibbaldioides* subsp. *elongatum* the cymules have only a short peduncle. Additionally, leaves of *G. alonsoi* are glabrous or have scattered hairs abaxially and on the margin, and are less deeply divided than those of *G. sibbaldioides* subsp. *elongatum*, which has abundant hairs at least abaxially. The fruits of *G. alonsoi* are shorter than those of *G. sibbaldioides* subsp. *elongatum*. *Geranium costaricense* also resembles *G. alonsoi*; however, the differences between them becomes apparent on closer inspection. In *G. costaricense* the leaf segments are

3-9-lobed at the apex and not deeply divided, the cymules are short (ratio cymule length/leaf length = 0.4-1.4), and the rostrum has a narrowed apex. In contrast, *G. alonsoi* has the leaf segments 1(3)-lobed at the apex and deeply divided, the cymules are long [ratio cymule length/leaf length = (1.9)2.6-4.2], and the rostrum lacks a narrowed apex. In addition, the geographical ranges of *G. costaricense* and *G. alonsoi* do not overlap; *G. costaricense* is endemic to Costa Rica and Panama.

**168. *Geranium costaricense*** H.E. Moore, Gentes Herb. 8(3): 253. 1951. *Geranium cucullatum* var. *multifidum* Suess., Bot. Jahrb. Syst. 72: 276. 1942. **Discussion.** *Geranium costaricense* has been considered closely allied with *G. sibbaldioides* (Burger, 1991: 18; Moore 1951: 253), a stemless species from Andes that is readily distinguished by its leaves. *Geranium sibbaldioides* has leaf laminae 0.4-1.3 cm long (1.5-2.8 cm long in *G. costaricense*), with a middle segment 1-3(4)-lobed at apex (3-9-lobed in *G. costaricense*). The nearest populations of *G. sibbaldioides* to those of *G. costaricense* are in northern Colombia, separated by more than 800 km. In this area *G. sibbaldioides* is represented by subsp. *elongatum*, which has hairy leaves (at least adaxially), while *G. costaricense* has glabrous leaves, except on the margins. *Geranium costaricense* is also similar to *G. foreroi* and *G. paludosum*, both restricted to northern Colombia. *Geranium costaricense* has much larger and more deeply divided leaves than *G. foreroi* and *G. paludosum*, and also a distinctive fruit feature: a rostrum with a narrowed apex 0.5-1 mm long, which is absent in the fruits of *G. foreroi* and *G. paludosum*.

Fig. 428. Distribution of *Geranium costaricense*.

BH)". TYPE: Ecuador. Azuay, Páramo del Castillo, 2°48'S, 78°37'W, 31 Aug. 1945, *W.H. Camp E-5138* (holotype, NY-00468263!; isotype, BH!).

**Perennial herbs**, 2-9 cm tall. **Root-stock** 2-6.8 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** scapiform, cushion-like, stolons absent, with short vegetative stems. **Basal leaves** in a persistent rosette; leaf laminae 0.35-1 cm long, 0.62-1.6 cm wide, not peltate, deeply palmatifid, tripartite [ratio main-sinus length/middle segment length = 0.86-0.92], triangular in outline, base rounded, not coriaceous, with nerves not projected, densely hairy on adaxial surface and usually on abaxial surface; segments 3(5), in 1 plane, middle segment broadly lanceolate, 0.5-1.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.09-0.16], entire; petioles up to 4 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent (sometimes retrorse, appressed), eglandular hairs 0.2-0.5 mm long; stipules 5.6-10 mm long, 0.9-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.2-0.4 mm long). **Cymules** 1-flowered, solitary [ratio cymule length/leaf length = 0.7-1.1]; peduncles 4-11 mm long, with patent, eglandular hairs 0.2-0.4 mm long; bracteoles 4-7 mm long, 0.5-1 mm wide, linear-lanceolate, opposite; pedicels absent or 7-30 mm long, with patent, eglandular hairs 0.2-0.5 mm long. Flowers actinomorphic. **Sepals** 4.3-5.6 mm long, 1.5-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.8 mm long [ratio mucro length/sepal length = 0.16-0.20], with erect-patent, eglandular hairs 0.1-0.5 mm long on base of abaxial surface and margin, glabrous adaxially, ending in 1-3 bristles 0.2-0.6 mm long.

**Petals** 6-9 mm long, 2.2-3.5 mm wide, erect-patent, rounded, without claw, purple or white, glabrous.

**169. *Geranium campii*** H.E. Moore, *Brittonia* 15: 92, 93 fig. 1. 1963. TYPE LOCALITY: "ECUADOR: Azuay: Páramo and sub-páramo area north and northwest of the Páramo del Castillo (ca. 6-8 km n n e of Sevilla de Oro); alt. 10000-11200 ft, 31 Aug 1945 W. H. Camp E-5138 (Holotype, NY; isotype,

Fig. 431. Distribution of *Geranium campii*.

gaard & al. 58262 (AAU). **Peru.** CAJAMARCA: Jaén, cerro arriba de Aguas Verdes, 6°50'S, 77°51'W, 10 Nov. 1999, Díaz & Campos 10950 (MA, MO).

**Discussion.** As Moore (1963: 92) pointed out, *G. campii* is similar to *G. sibbaldioides* but differs in the tripartite leaf-blades that are hairy at least adaxially, in the usually patent hairs on petioles and peduncles, and in

the hairy sepals. The circumscription of *G. campii* presented in Aedo & al. (2002: 234) is here expanded to include plants with the leaves mainly tripartite and with broadly lanceolate segments. Some specimens have a few leaves with 4(5) segments. Leaf indumentum also varies from densely hairy on both surfaces to hairy only adaxially. *Geranium campii* is endemic to southern Ecuador and northern

Peru, where it is sympatric with *G. sibbaldioides* in similar wet habitats in the paramos. Some intermediate specimens with a variable combination of characters, including leaves with five segments and hairy only adaxially, petioles and peduncles with retrorse hairs, and almost glabrous sepals have been collected in this region. These plants cannot be readily assigned to either *G. campii* or *G. sibbaldioides*. Additional collections and a focused field study may help to elucidate this variability, which may be a result of hybridization. During field studies, both species were found growing on the same cushion (Aedo 13220: *G. campii*; Aedo 13221: *G. sibbaldioides* subsp. *sibbaldioides*) without intermediate forms.

**170. *Geranium rhomboidale*** H.E. Moore, Gentes Herb. 8: 255, 256 fig. 103. 1951. TYPE LOCALITY: "Colombia: comisaría del Putumayo; Páramo de San Antonio, entre La Laguna de La Concha y el Valle de Sibundoy, alt. ca. 3000-3200 m., February 13, 1942, R. E. Schultes 3238 (BH. type); alta cuenca del Río Putumayo, filo de la cordillera entre El Encano y Sibundoy; Páramo de San Antonio de Bordoncillo, alt. 3250 m., January 4, 1941, J. Cuatrecasas 11741 (US.); road from Sibundoy to Pasto, between La María and Páramo de San Antonio, alt. 2900-3180 m., June 1, 1946, Schultes & M. Villarreal 7825 (BH.)". TYPE: Colombia. Putumayo, Páramo de San Antonio, entre La Laguna de La Concha y el Valle de Sibundoy, 1°10'N, 77°00'W, 13 Feb. 1942, R.E. Schultes 3238 (holotype, BH!; isotypes, GH-00055015!, ILL-00006672 image!).

*Perennial herbs*, 2-5 cm tall. *Rootstock* 2.4-5 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.5-0.8(1.2) cm long, 0.5-1(1.6) cm wide, not peltate, digitate (lateral segments upward) [ratio main-sinus length/middle segment length = 0.55-0.75], polygonal to obtriangular in outline, base rounded to cuneate, ± coriaceous, with nerves not projected, glabrous on both surfaces, with patent, eglandular cilia 0.4-0.8 mm long on the margin, each segment ending in 1-2 bristles 0.5-0.8 mm long; segments 3(5), in 1 plane, middle segment obtriangular (with lanceolate lobes), 1.4-2.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.24-0.36], (2)3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.08-0.26]; petioles up to 2.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse to retrorse-appressed, eglandular

hairs 0.2-0.5 mm long; stipules 5.2-13 mm long, 0.9-1.5 mm wide, lanceolate (with a setaceous apex 0.7-5 mm long), free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.4-0.8 mm long). *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.9-1.4]; peduncles 4-20 mm long, with retrorse to retrorse-appressed, eglandular hairs 0.3-0.6 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 5.5-8 mm long, 1.5-2.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.9 mm long [ratio mucro length/sepal length = 0.05-0.16], with erect-patent, eglandular hairs 0.4-1 mm long on margin (sometimes on the base of abaxial surface), glabrous adaxially, ending in 1-2 bristles 0.4-0.6 mm long. *Petals* 8.5-13.6 mm long, 2.2-5.6 mm wide, erect-patent, rounded, without claw, purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.5-4.1 mm long, lanceolate, yellow, glabrous or with scattered hairs 0.1-0.2 mm long; anthers 0.6-0.7 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-4.1 mm long, yellow. *Fruit* 8-11 mm long, erect, discharge of seed-ejection type; mericarps 1.3-2.2 mm long, 0.8-1.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, glabrous or with antrorse, ± appressed, eglandular hairs 0.1-0.2 mm long; rostrum 4.5-8 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.7-1.2 mm long, with 5 glabrous lobes. *Seeds* 1.4-1.5 mm long, 0.8-0.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 432, 433.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to November.

*Distribution*. This species ranges through central and southwestern Colombia (Figs. 434).

*Habitat*. Mossy and wet places with *Espeletia* Mutis ex Bonpl. and grassy tussock; 2900-3600 m.

*Additional specimens examined*. **Colombia**. *Discussion*. *Geranium rhomboidale* is characterized by digitate leaf blades with usually three segments. The lateral segments are directed

upwards and the middle segment is 3-lobed. The leaves are glabrous but have patent long cilia on the margin. As reported by Moore (1951: 257), *G. azorelloides*, *G. jahnii*, and *G. maniculatum* closely resemble *G. rhomboidale* but differ in leaf characters. *Geranium jahnii* has very nar-

row leaves that are apically tridentate and have an articulated petiole; *G. azorelloides* is quite similar to *G. jahnii* but without an articulated petiole. In *G. maniculatum* the leaves have the middle leaf segment entire and are glabrous or bear short, antrorse hairs.

Cajamarca, Minas Conga, sector El Águila, 6°51'S, 78°21'W, 4 Oct. 2005, *Granda* 2513 (MA).

*Discussion*. *Geranium maniculatum* is characterized by the digitate leaf blade with usually five segments. The lateral segments are directed upwards, and the middle segment is entire and lanceolate. The leaves are usually glabrous, but some specimens have short antrorse hairs on

the margin. *Geranium sibbaldioides* and *G. rhomboidale* are two species similar to *G. maniculatum*. *Geranium sibbaldioides* subsp. *sibbaldioides* may be distinguished by leaf characters: the lateral segment directed upward, the middle segment narrowly lanceolate, and the margin usually glabrous. *Geranium sibbaldi-*

*oides* subsp. *elongatum* is easily recognized by its hairy leaves, while *G. sibbaldioides* subsp. *beckianum* has a middle segment that is 3-lobed at the apex. In *G. maniculatum* the fruit and the sepal mucro are shorter than in *G. rhomboidale*. Other leaf features that distinguish them are noted under *G. rhomboidale*.

Kirkbride 635 (holotype, COL-191289!; isotype, NY-01364985!).

635 (COL-191289!)". TYPE: Colombia. Magdalena, Sierra Nevada de Santa Marta, 1 km al NW de la quebrada de la laguna Río Frío, en dirección al pico José Hilario, 10°55'N, 73°53'W, 31 July 1972, E. Forero & J.H. Kirkbride 635 (holotype, COL-191289!; isotype, NY-01364985!).

*Perennial herbs*, 2-8 cm tall. *Root-stock* 2.5-4 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.9-2.3 cm long, 1.3-2.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.70-0.86], polygonal in outline, base cordate, not coriaceous, with nerves not projected, glabrous on both surfaces, with antrorse, eglandular cilia 0.1-0.4 mm long on the margin, usually each segment ending in 1-3 bristles 0.2-0.5 mm long; segments 5, in 1 plane, middle segment obtriangular (with linear-lanceolate lobes), 1-1.9 mm wide at the base [ratio segment width at the base/middle segment length = 0.12-0.14], 3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.26-0.34]; petioles up to 4 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-0.7 mm long; stipules 6-13.7 mm long, 0.9-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.2-0.5 mm long). *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 1-1.3]; peduncles 20-31 mm long, with patent, eglandular hairs 0.1-0.7 mm long; bracteoles absent.

Fig. 438. *Geranium foreroi*. a. Habit. b. Flowering branch. c. Leaf. d. Leaf lobe. e. Peduncle. f. Flower. g. Petal. h. Staminal filament. i. Fruit. j, k. Mericarps. l. Seed. (Based on: Forero & Kirkbride 635, COL).

Fig. 439. Distribution of *Geranium foreroi*.

Flowers actinomorphic. *Sepals* 6.5-8.7 mm long, 2-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 5, mucro 0.4-0.9 mm long [ratio mucro length/sepal length = 0.10-0.12], with erect-patent, eglandular hairs 0.2-0.7 mm long on the abaxial surface and margin, glabrous adaxially. *Petals* 15-18 mm long, 5.1-7 mm wide, erect-patent, rounded, without claw, white, hairy on the base of the adaxial surface and margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.4-5.5 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 0.9-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.9-5 mm long, unknown color. *Fruit* 9-11 mm long, erect, discharge of seed-ejection type; mericarps ca. 2.3 mm long, 1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long; rostrum ca. 7 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1 mm long; stigmatic remnants 0.7-1 mm long, with 5 glabrous lobes. *Seeds* ca. 1.6 mm long, 0.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 438.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in July.

*Distribution*. This species is endemic to northern Colombia (Fig. 439).

*Habitat*. Unknown, probably on *Espeletia* Mutis ex Bonpl. paramo; 3300-3400 m.

*Additional specimens examined*. **Colombia**. MAGDALENA: Sierra Nevada de Santa Marta, cabeceras del río Sevilla, 10°53'N, 73°57'W, 20 Jan. 1959, *Barclay & Juajibioy* 6637 (COL, MO).

*Discussion*. *Geranium foreroi* has petioles and pedicels with patent, eg-

landular hairs 0.1-0.7 mm long and petals 15-18 mm long. This species could be confused with *G. paludosum*, which has retrorse short hairs (0.1-0.3 mm long) on the petioles and pedicels, and shorter petals (10.5-15.5 mm long). In both species the petals are adaxially hairy at the base and on the margin, an unusual feature among stemless species from the Andes. For differences between *G. foreroi* and *G. costaricense*, see that species. The only two collections of *G. foreroi* are from Sierra Nevada de Santa Marta, where *G. paludosum* also grows. The species are apparently allopatric; *G. foreroi* has been found in the north-western part of this mountain range, and *G. paludosum* was collected on the central and eastern slopes.

**173. *Geranium paludosum*** R. Knuth, Repert. Spec. Nov. Regni Veg. 28: 2. 1930. TYPE LOCALITY: "Colombia: Sierra Nevada de Santa Marta, Siminchuená-Adurimeira, an moorigen Stellen (A. Schultze a. 1928 n. 1314 -- Typus in herb. Berol.). -- Blühend Februar". TYPE: Colombia. Sierra Nevada de Santa Marta, Siminchuená-Adurimeira, 1928, A. Schultze 1314 (holotype, B destroyed). Colombia. Magdalena, Sierra Nevada de Santa Marta, valley descending southwestern from Picos Reina and Ojeda, around laguna Naboba, Laguna Mamito and Laguna Mamo, 10°39'N, 73°37'W, 3 Oct. 1959, *J. Cuatrecasas & R. Romero* 24578 (neotype, designated by Aedo & al. 2002: 261, COL-000001793!).

*Perennial herbs*, 2-7 cm tall. *Rootstock* 3-5 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, sometimes with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.8-1.3 cm long, 0.9-1.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.70-0.81], polygo-

nal in outline, base cordate, not coriaceous, with nerves not projected, glabrous on both surfaces, with antrorse, eglandular cilia 0.1-0.2 mm long on the margin; segments 5, in 1 plane, middle segment obtriangular (with linear-lanceolate lobes), 0.8-1.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.16-0.18], 3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.16-0.27]; petioles up to 5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; stipules 5-10.4 mm long, 1-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.2-0.3 mm long). *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.7-1.1]; peduncles 8-40 mm long, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 5.5-7.9 mm long, 1.5-3.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.7 mm long [ratio mucro length/sepal length = 0.08-0.09], with erect-patent, eglandular hairs 0.2-0.4 mm long on the abaxial surface and margin, glabrous adaxially. *Petals* 10.5-15.5 mm long, 3.3-7 mm wide, erect-patent, rounded, without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.5-4.1 mm long, lanceolate, yellow, with eglandular hairs 0.1-0.3 mm long on the abaxial surface and margin; anthers 0.8-1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.5-4 mm long, yellow. *Fruit* 10.1-12 mm long, erect, discharge of seed-ejection type; mericarps 1.9-2 mm long, 0.7-1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs ca. 0.1 mm

long; rostrum 7.4-9 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1 mm long; stigmatic remnants 0.9-1.1 mm long, with 5 glabrous lobes. *Seeds* 1.4-2 mm long, 0.9-1 mm wide, finely reticulate, uniformly colored, brown,

glabrous. Cotyledons with entire margin. Fig. 440.

*Pollen.* *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from May to December.

*Distribution.* This species is endemic to northern Colombia (Fig. 441).

*Habitat.* Paramo and upper montane forests; 3200-4500 m.

*Additional specimens examined. Colombia.* MAGDALENA: Sierra Nevada de Santa Marta, 1954, *College West Indies Exped.* 22 (US); Sierra Nevada de Santa Marta, 1880, *Simons s.n.* (BM); Sierra Nevada de Santa Marta, caserío de San Sebastián-Bellavista, 10°36'N, 73°37'W, 7 Dec. 1980, *Rangel & al.* 1881 (COL); Sierra Nevada de Santa Marta, valle del río Donachuy, camino Corisa-Naboba lake, 10°38'N, 73°30'W, 15 Oct. 1958, *Hammen* 1179 (COL, MA); Sierra Nevada de Santa Marta, río Guiachinacopunamaina, 10°44'N, 73°40'W, 28 May 1977, *White & Alverson* 624 (COL, MO, NY); Sierra Nevada de Santa Marta, SE slopes, Hoya del río Donachuí, laguna de Calocribe, eastern of Meollaca, 10°46'N, 73°31'W, 30 Sep. 1959, *Cuatrecasas & Romero* 24555 (COL); Sierra Nevada de Santa Marta, source of río Donachuy, 10°48'N, 73°39'W, 21 May 1977, *White & Alverson* 532 (COL).

*Discussion.* *Geranium paludosum*, an endemic of Sierra Nevada de Santa Marta of northern Colombia, is readily recognized by its small and shallowly divided leaf laminas. It also has sepals with a short mucro and long petals that are basally hairy. In herbarium specimens the leaves are almost black. The lectotype proposed by Knuth (1930a: 2) is lost and no duplicates were found. Therefore, a neotype collected near the type locality and in agreement with the original description was designated.
