*Geranium guamanense* Halfd.-Niels., Nordic J. Bot. 16(3): 271 fig. 3. 1996. TYPE LOCALITY: "Øllgaard & Balslev 10064, Ecuador, Prov. Napo, road Quito-Baeza, Páramo de Guamaní, 1 km along take-off road to telecommunication antenna in the pass, bunch grass páramo and boggy páramo, shrub in protected places (78°09'W, 0°17'S), alt. 4000-4100 m, 7-9 Oct 1976 (AAU holotype, NY isotype)". TYPE: Ecuador. Napo, road Quito-Baeza, Páramo de Guamaní, 0°17'S, 78°09'W, 7-9 Oct. 1976, B. Øllgaard & H. Balslev 10064 (holotype, AAU!; isotypes, MO!, NY-00076862!).

*Perennial herbs*, 2-14 cm tall. *Root-stock* 1.3-6 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, sometimes with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.9-2.4 cm long, 1-2.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.63-0.80], orbicular in outline, base cordate, ± coriaceous,

nerves ± projected on the abaxial surface, sunken adaxially, glabrous to pilose with antrorse, appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular (with lanceolate lobes), 1.6-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.21-0.31], 3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.13-0.26]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, glabrous or with patent, eglandular hairs 0.2-1.3 mm long; stipules 8.8-60 mm long, 1.4-6 mm wide, lanceolate, obtuse (setaceous apex 1.3-6 mm long), free, scarious, stramineous, glabrous on both surfaces, ending in 1-3 bristles 0.3-0.9 mm long. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.4-0.5(1)]; peduncles (4)8-20(40) mm long, glabrous or pilose, with patent, eglandular hairs 0.2-1 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* (5.6)8-9 mm long, 1.5-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-0.8 mm long [ratio mucro length/sepal length = 0.07-0.12], with erect-patent, eglandular hairs 0.5-1.1 mm long on the abaxial surface (sometimes glabrous) and margin, glabrous adaxially. *Petals* (8.3)9-14 mm long, 2.3-5 mm wide, erect-patent, rounded, without claw, purple, sometimes white, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.8-5 mm long, lanceolate with an abruptly narrowed apex, white, glabrous, or with eglandular hairs 0.1-0.2 mm long on the abaxial surface and margin; anthers 0.6-0.8 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-5.2 mm long, purple. *Fruit* 10-12.6 mm long, erect, discharge of seed-ejection type; mericarps 1.8-3.1 mm long, 1-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse, ± appressed, eglandular hairs 0.1-0.5 mm long on the sur-

face and eglandular hairs 0.5-0.7 mm long on the margin; rostrum 6-8 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 0.7-2 mm long, with 5 glabrous lobes. *Seeds* 1.5-1.8 mm long, 0.8-1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 442, 443.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to November.

*Distribution*. This species ranges from central Colombia to central Ecuador (Fig. 444).

*Habitat*. Grassy areas and boggy paramo among cushions and tuft of grasses; 1700-4300 m.

*Representative specimens examined*.

**Discussion.** *Geranium stramineum* can be distinguished from all other stemless species from the Andes by its stramineous and scarious stipules, which become frayed at the margin with time. These stipules are obtuse with a setaceous apex 3-6 mm long. In other stemless species, the stipules are usually papery, reddish, lanceolate, and sometimes have a setaceous apex (which usually ends in 1-3 bristles). *Geranium stramineum* can be glabrous or have more or less abundant hairs on the petiole and on the leaf lamina. Hairy forms have been described as *G. confertum*, *G. angelense*, and *G. guamanense*; however, many transitional specimens combine the glabrous to hairy forms, and I am reluctant to accord these forms specific recognition. For example, *Barclay* 6399 (MO) has a glabrous petiole and hairs only on the leaf margin, and *Halfdan-Nielsen & León* 74 (QCA) has a hairy petiole and hairs on the leaf margin and on the nerves of the abaxial surface. The collection *Lozano & al.* 4591 (COL) includes glabrous specimens and some that are quite hairy on the petiole and on the lamina, whereas in a duplicate sheet at F all specimens are hairy. The sepal and petal length are variable, and do not show any correlation with the indumentum. Moreover, hairy and glabrous forms both occur over the entire range of this species. The collection *Macbride* 4401 is labeled as collected in central Peru, but the two sheets at G and MA are *G. multipar-*

*titum*, and the one at NY includes a fragment of *G. stramineum*. The gathering was probably mislabeled, and the presence of *G. stramineum* in Peru remains to be confirmed.

**175. *Geranium ecuadoriense*** Hieron., Bot. Jahrb. Syst. 20, Beiblatt 49: 30. 1895. TYPE LOCALITY: "Ecuador: crescit locis arenosis montis Chimborazo, alt. s.m. 4000 m, ad limitem nivis aeternae, mense Junio florens (n. 6642)". TYPE: Ecuador. Chimborazo, Mt. Chimborazo, 1°28'S, 78°47'W, *F.C. Lehmann* 6642 (lectotype, designated by *Aedo & al.* 2002: 245, K!; isolectotype, BH-418691-fragment!).

*Perennial herbs*, 1.3-5 cm tall. *Root-stock* 3-17 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.4-0.8 cm long, 0.5-1.1 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, sericeous on both surfaces; segments 7, in more than 1 plane, middle segment obtriangular (with lanceolate lobes), 0.4-0.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.18], 3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.40-0.76]; petioles up to 3 cm long, without abscission zone, terete, not swollen, not deflexed in age, sericeous, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-1 mm long; stipules 4.5-12 mm long, 1-2.3 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.3-0.6 mm long). Cymules 1-flowered, solitary [ratio cymule length/leaf length = 1-1.2]; peduncles 5.2-11 mm long, sericeous, with retrorse,  $\pm$  appressed, eglandular hairs 0.2-0.6 mm long; bracteoles absent. Flowers acti-

nomorphic. *Sepals* 4.1-8.2 mm long, 1.5-3.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.9 mm long [ratio mucro length/sepal length = 0.10-0.13], sericeous with erect-patent, eglandular hairs 0.2-0.5 mm long on the abaxial surface and patent, eglandular hairs 0.6-1.5 mm long on the margin, hairy adaxially. *Petals* 6.7-10 mm long, 1.7-3.9 mm wide, erect-patent, rounded, without claw, white to pink, glabrous on the adaxial surface and margin, hairy on the base of the abaxial surface, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.8-3.6 mm long, lanceolate, white, with eglandular hairs 0.2-0.4 mm long on the abaxial surface and margin; anthers 0.7-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.3-4.5 mm long, yellow. *Fruit* 10-14.4 mm long, erect, discharge of seed-ejection type; mericarps 2.2-3.8 mm long, 1-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.8 mm long; rostrum 6.3-8.2 mm long, without a narrowed apex, not twisted, sericeous, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 1-2 mm long, with 5 hairy lobes. *Seeds* 1.6-2.3 mm long, 0.8-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 445, 446.

*Pollen.* *Geranium*-type (*Aedo & al.* 2002: 217).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from June to January.

*Distribution.* This species is endemic to central Ecuador (Fig. 447).

*Habitat.* Sandy or gravelly paramo, with occasional cushion plants and scattered shrubs of *Loricaria* Wedd.; 3800-4600 m.

**Discussion.** *Geranium ecuadoriense*, an endemic of Ecuador, is known only from a small area near Volcán Chimborazo and localities near Quito. Among the stemless species from the Andes, *G. ecuadoriense* somewhat resembles *G. tovarii* and *G. weddellii* in its deeply divided, short, sericeous leaves. *Geranium ecuadoriense* has petioles and pedicels with retrorse hairs and petals abaxially basally hairy, whereas *G. tovarii* and *G. weddellii* have the petioles and pedicels with antrorse hairs and glabrous petals. In addition, *G. ecuadoriense* shares with *G. tovarii* sepals with long, patent, hairs on the margin and glabrous nectaries. *Geranium ecuadoriense* has been confused sometimes with depauperate forms of *G. diffusum*, which also grows in the Chimborazo area. Yet, leaves of

Fig. 446. *Geranium ecuadoriense* (Based on: Aedo 13228, MA).

Fig. 447. Distribution of *Geranium ecuadoriense*.

*G. ecuadoriense* differ in that the seven segments are held in two planes: the two basal segments are more or less perpendicular to the remaining ones. Additionally, *G. diffusum* is not sericeous, although it sometimes has a dense indumentum, and has prostrate to ascending (sometimes short) stems with internodes that are not covered by stipules.

**176. *Geranium multipartitum* Benth.**, Pl. Hartw. 2: 166. 1845. TYPE LOCALITY: "Hacienda de Antisana". TYPE: Ecuador. Pichincha, near the hacienda de Antisana, 0°30'S, 78°10'W, K. Hartweg s.n. (lectotype, designated by Knuth 1912: 86, K!).

*Perennial herbs*, 2-7(16) cm tall. *Rootstock* 4-8 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, sometimes with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.7-1.7(2.7) cm long, 0.8-1.8(3) cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  scattered subpatent, eglandular hairs on both surfaces (rarely glabrous), each segment usually ending in 1-3 bristles 0.5-0.7 mm long; segments 9, in more than 1 plane, middle segment rhombic (with linear-lanceolate lobes), 0.4-1 mm wide at the base [ratio segment width at the base/middle segment length = 0.03-0.06], 3-5(9)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.57-0.68]; petioles up to 8 cm long, without abscission zone, ter-

ete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1.1 mm long, sometimes glabrous; stipules 6.7-12.6 mm long, 1-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially (ending in 1-3 bristles 0.4-0.5 mm long). *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.6-1.8]; peduncles 5-14(31) mm long, with patent, eglandular hairs 0.2-1 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 5-8.3 mm long, 1.2-2.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-1 mm long [ratio mucro length/sepal length = 0.12-0.16], with  $\pm$  patent, eglandular hairs 0.2-1.6 mm long on both surfaces, sometimes patent, eglandular hairs 1-2.2 mm long on the margin, rarely ending in 1-1-2 bristles 0.3-0.4 mm long. *Petals* 5.2-7.4(10.2) mm long, 2.2-2.9 mm wide, erect-patent, rounded, without claw, purple, sometimes white, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.5-4.4 mm long, lanceolate with an abruptly narrowed apex, white, glabrous on both surfaces, ciliate on the proximal half, with hairs 0.2-0.8 mm long; anthers 0.6-1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-3.6 mm long, yellow. *Fruit* 9.7-13.5 mm long, erect, discharge of seed-ejection type; mericarps 2-3.4 mm long, 1-1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-0.5 mm long on the surface and eglandular hairs 0.4-0.6 mm long on the margin; rostrum 5.6-8.1 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 1.3-2 mm long, with 5 glabrous lobes. *Seeds* 1.6-2.1 mm long, 1-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 448, 449.

*Pollen.* *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from January to December.

*Distribution.* This species ranges from Colombia, through Ecuador and Peru to western Bolivia (Fig. 450).

*Habitat.* Bogs, rocky slopes, among grass tussocks, paramo dominated by cushions of *Azorella* Lam. and *Planta-*

*go* L., and *Polylepis* Ruiz & Pav. forests; 1650-4700 m.

*Representative specimens examined.*

**Discussion.** *Geranium multipartitum* can be distinguished from all other species treated here by its palmatisect leaves with nine segments and with ±

scattered eglandular, subpatent hairs on both surfaces (but sometimes glabrous). It should be noted that the pair of basal segments is more or less perpendicular to the plane formed by the remaining segments of the leaf. *Geranium multipartitum* also has petioles and pedicels bearing patent, eglandular hairs. It has been frequently confused with *G. humboldtii*, a species characterized by its glabrous pedicels, and by its palmatisect leaves with seven segments, which are sericeous adaxially and glabrous abaxially. Two collections from Colombia (Depto. del Valle, *Cuatrecasas* 20083, 20550) have glabrous pedicels but otherwise are similar to other specimens of *G. multipartitum*. A specimen from Ecuador (Prov. Pichincha, *Barclay* & *Juajibioy* 8894) has leaves that are densely hairy adaxially, somewhat like *G. humboldtii*; however, the laminae have nine segments and agree with *G. multipartitum*. *Geranium heinrichsae* was based on *Heinrichs* s.n. (B), which was destroyed during the Second World War. Unfortunately, no duplicate of this collection has been found. Jørgensen & León (1999: 492) list the name as a synonym of *G. multipartitum*, an assignment that agrees with the original description (Knuth 1936: 216).

*Perennial herbs*, 2-8 cm tall. *Root-stock* 2-12 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae (0.6)1.1-1.5 cm long, 0.7-1.6 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, sericeous on the adaxial surface, with antrorse, appressed, eglandular hairs and glabrous abaxially; segments 7, in more than 1 plane, middle segment rhombic (with linear-lanceolate lobes), 0.4-1.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.06-0.19], 3(4)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.44-0.66]; petioles up to 7 cm long, without abscission zone, terete, not swollen, not deflexed in age, usually glabrous, sometimes with scattered, patent, eglandular hairs 0.8-1.2 mm long; stipules 5.1-14 mm long, 1.3-3 mm wide, lanceolate, free, papery, brownish red, glabrous on both surfaces, with patent, eglandular ciliae 0.2-0.3 mm long, ending in 1-2 bristles 0.3-0.8 mm long. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.6-0.9]; peduncles 3.3-6 mm long, glabrous; bracteoles absent. Flowers actinomorphic. *Sepals* 5.7-7.5 mm long, 1.7-2.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-0.6 mm long [ratio mucro length/sepal length = 0.09-0.12], glabrous or with scattered, eglandular hairs abaxially, erect-patent, eglandular hairs 0.2-1 mm long on the margin and adaxially. *Petals* (6.6)8.5-11 mm long, 1.6-4 mm wide, erect-patent, rounded, without claw, white to pink, usually glabrous, sometimes hairy on the basal 1/4 of their adaxial surface, gla-

brous abaxially, ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.9-4 mm long, lanceolate or lanceolate with an abruptly narrowed apex, white, glabrous,

or with eglandular hairs 0.2-0.4 mm long on the abaxial surface and margin; anthers 0.7-1 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 4-5 mm long, yellow. *Fruit* 10.8-12 mm long, erect, discharge of

seed-ejection type; mericarps 2.2-3.1 mm long, 1.2-1.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.3 mm long; rostrum 5.6-7 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 1.1-1.9 mm long, with 5 hairy lobes. *Seeds* 1.6-1.9 mm long, 0.8-1.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 451, 452.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to December.

*Distribution*. This species ranges from central and northern Ecuador to northern Peru (Fig. 453).

**Discussion.** *Geranium humboldtii*  
can be distinguished from all oth-  
er species treated here by the pal-  
matisect leaves, which are adaxially  
white-sericeous and abaxially  
glabrous. All other "sericeous" and  
stemless species from the Andes have  
leaves with a dense indumentum on  
both surfaces. *Geranium humboldtii*  
has sometimes been confused with  
*G. multipartitum*, because both share  
deeply divided leaves (with basal  
segments in a perpendicular plane);  
however, *G. multipartitum* differs for  
*G. humboldtii* in that its leaves have  
± scattered, subpatent hairs on both  
surfaces (or are sometimes glabrous).  
A collection from Peru (Cajamarca,  
Sánchez & Castillo 6449) differs in its  
abaxially hairy instead of glabrous  
petals and lanceolate rather than  
subulate staminal filaments, but oth-  
erwise it matches other specimens of  
*G. humboldtii*.

with nerves not projected, pilose, with  
± scattered antrorse, appressed eg-  
landular hairs (on margin and nerves)  
on both surfaces; segments 7, in  
more than 1 plane, middle segment  
obtriangular (with linear-lanceolate  
lobes), 1-1.2 mm wide at the base  
[ratio segment width at the base/  
middle segment length = 0.07-0.10],  
3-lobed in distal half [ratio second-  
ary sinus length/middle segment  
length = 0.54-0.65]; petioles up to 5  
cm long, without abscission zone, ter-  
ete, not swollen, not deflexed in age,  
with retrorse, appressed, eglandular  
hairs 0.2-0.4 mm long; stipules 9-12  
mm long, 1-1.5 mm wide, lanceolate,  
free, papery, brownish red, glabrous  
or with scattered, eglandular hairs.  
*Cymules* 1-flowered, solitary [ratio  
cymule length/leaf length = 0.6-0.7];  
peduncles 9-21 mm long, with ret-  
rorse, appressed, eglandular hairs  
0.2-0.4 mm long; bracteoles absent.  
Flowers actinomorphic. *Sepals* 6.5-6.7  
mm long, 2-2.2 mm wide, lanceolate,  
smooth, not accrescent, nerves 3,  
mucro 0.4-0.6 mm long [ratio mucro  
length/sepal length = 0.06-0.08], gla-  
brous on the abaxial surface, with  
scattered, eglandular hairs 0.2-0.4  
mm long on adaxial surface and  
erect-patent, eglandular hairs 0.4-0.6  
mm long on the margin. *Petals* 9.5-13  
mm long, ca. 4 mm wide, erect-pat-

Fig. 453. Distribution of *Geranium humboldtii*.

ent, rounded, without claw, purple, sometimes white, glabrous. *Stamens* 10, both whorls bearing anthers; filaments ca. 4 mm long, lanceolate with an abruptly narrowed apex, yellow, with eglandular hairs 0.2-0.5 mm long on the abaxial surface and margin; anthers ca. 1 mm long, purple. *Nectaries* 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 4-4.5 mm long, purple. *Fruit* 12-13 mm

long, erect, discharge of seed-ejection type; mericarps ca. 2.4 mm long, 1.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with scattered antrorse, eglandular hairs 0.2-0.5 mm long on margins and on the dorsal nerve; rostrum ca. 11 mm long, with a narrowed apex 1 mm long, not twisted, with erect-patent,

eglandular hairs 0.1 mm long; stigmatic remnants 2-2.5 mm long, with 5 glabrous lobes. *Seeds* ca. 1.7 mm long, 1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 454.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 216).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in April.

*Distribution*. This species is endemic to central Peru (Fig. 455).

*Habitat*. Wet and grassy stream slopes; ca. 3000 m.

*Discussion*. *Geranium macbridei* is only known from the type, a flowering and fruiting collection from Pasco, Peru. It is most similar to *G. multipartitum*. These two differ from all other stemless species from the Andes by their palmatisect leaves without sericeous vestiture. In *G. macbridei* the laminae have scattered antrorse, appressed hairs on the margin and on the nerves on both surfaces, whereas in *G. multipartitum* the leaves have scattered subpatent hairs on both surfaces (or rarely are glabrous). In *G. macbridei* the petioles and pedicels bear retrorse, appressed hairs 0.2-0.4 mm long, whereas those of *G. multipartitum* have patent hairs 0.2-1.1 mm long (or are rarely glabrous). *Geranium macbridei* is also easy to differentiate from *G. multipartitum* by its much longer petals, hairy nectaries, and fruits with a narrowed apex.

dorsally glabrous. *Gynoecium* 4.9-5.8 mm long, yellow. *Fruit* 11.7-14.6 mm long, erect, discharge of seed-ejection type; mericarps 2.6-2.7 mm long, 1.7-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs ca. 0.5 mm long on the basal margin; rostrum 7.9-9.1 mm long, without a narrowed apex, not twisted, glabrous; stigmatic remnants 1-2.1 mm long, with 5 glabrous lobes. *Seeds* ca. 2.1 mm long, 1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 456.

*Pollen.* *Geranium*-type (Aedo 2012: 10).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from June to November.

*Distribution.* This species is endemic to northern Peru (Fig. 457).

*Habitat.* Paramo-like zones called "jalca", in rocky or wet grassy places; 4000-4100 m.

*Additional specimens examined.* **Peru.** ANCASH: Huari, Juprog, entre el caserío y la laguna, 9°34'S, 77°33'W, 24 Nov. 2006, Cano & al. 17209 (MA). LA LIBERTAD: Santiago de Chuco, jalca de Coipín, 7°46'S, 78°3'W, 16 June 1984, Sagastegui & al. 11975 (F, MO).

*Discussion.* *Geranium sagasteguii* is a rare endemic of Peru. Among the species of *Geranium* in South

America, it resembles most closely *G. paludosum*, from which it is easy to differentiate by its usually glabrous pedicels, glabrous and longer petals, longer sepals that are hairy only on a line near each margin (not on the entire abaxial surface), nectaries with a tuft of hairs at the apex, and glabrous staminal filaments. The leaves are quite similar in both species, palmatifid and almost glabrous; yet, on closer inspection, differences become apparent: *G. paludosum* has narrow lobes and patent hairs on the margin, while *G. sagasteguii* has wide lobes and antrorse, appressed hairs. In addition, the geographical ranges of the two species do not overlap; *G. paludosum* is endemic to Sierra de Santa Marta of northern Colombia. *Geranium sagasteguii* could be confused with some specimens of *G. sessiliflorum* from northern Peru that have leaves not as deeply lobed and almost glabrous (hairs restricted to margins and nerves of the abaxial surface). These specimens, however, can easily be identified as *G. sessiliflorum* by the sepals, which bear long, patent hairs on the margins (more or less pectinate). In *G. sagasteguii* the hairs on the sepals are antrorse, appressed, and restricted to a narrow marginal line. One specimen of *G. sagasteguii* collected in Ancash (A. Cano & al. 17209) has sepals and petals a bit shorter than those collected at the type locality and pedicels with scattered retrorse hairs, but it otherwise matches the type of *G. sagasteguii*.

**180. *Geranium jaekelae*** J.F. Macbr., Candollea 6: 7. 1934, [-XII-1934]. *Geranium minimum* R. Knuth, Bot. Jahrb. Syst. 37: 567. 1906, nom. illeg., non Cav. 1787. TYPE LOCALITY: "Peru: Dep. *Discussion*. *Geranium jaekelae*, a rare endemic from central Peru, differs from sympatric scapiform species by its small leaves with entire to three lobed segments and antrorsely hairy petioles and pedicels. It also has short cymules, reduced to a 1-flowered peduncle without bracteoles. The original material (*Weberbauer*

2623) has glabrous leaves, except for some antrorse cilia on the margin. The other known collections show sparse hairs on both surfaces. *Geranium jaekelae* approaches some forms of *G. sessiliflorum*; however, *G. jaekelae* differs for *G. sessiliflorum* in that its

leaves are smaller, less deeply divided and usually with entire segments and that its petioles and pedicels are antrorsely hairy. Additionally, *G. jaekelae* lacks the characteristic turnip-shaped rootstock and sepals with pectinate margin of *G. sessiliflorum*.

hairs 0.3-0.6 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 4.2-6.3 mm long, 1.3-2.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.6 mm long [ratio mucro length/sepals length = 0.04-0.13], sericeous with erect-patent, eglandular hairs 0.2-0.5 mm long on the abaxial surface and patent, eglandular hairs 1-1.4 mm long on the margin, glabrous adaxially. *Petals* 5.2-10.5 mm long, 1.4-4.5 mm wide, erect-patent, rounded, without claw, white, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.4-5 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.6 mm long on the abaxial surface and margin; anthers 0.7-0.8 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.6-4.5 mm long, yellow. *Fruit* 6.5-10.5 mm long, erect, discharge of seed-ejection type; mericarps 2.3-3.7 mm long, 1.3-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.5 mm long; rostrum 4-7 mm long, without a narrowed apex, not twisted, sericeous, with antrorse, appressed, eglandular hairs 0.2-0.5 mm long; stigmatic remnants 0.5-1.4 mm long, with 5 hairy lobes. *Seeds* 1.4-2.1 mm long, 0.7-1.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 463.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to April.

*Distribution*. This species ranges from central to eastern Peru (Fig. 464).

*Habitat*. Rocky outcrops in puna; 4000-4650 m.

*Additional specimens examined*. **Peru**. vallibus cordilleriis, 1790, *Haenke s.n.* (PR). *Discussion*. *Geranium crassipes* is easily distinguished from most of the sericeous, stemless, Andean species by its palmatifid leaves, sericeous on both surfaces and with entire segments. It is quite similar to *G. planum*, from which it differs principally in its mucro-tipped sepals with long, patent hairs on the margin; the hairs on petioles and peduncles are also longer than in *G. planum*. *Geranium crassipes* might be mistaken at first glance for *G. nivale*, but it has fruit without a narrowed apex, and shorter leaf laminas and petals. Knuth (1912: 83) considered *G. crassipes* a synonym of *G. sessiliflorum*, although he did not see any type material. In my view, *G. sessiliflorum* is easy to differentiate from *G. crassipes* by its turnip-shaped rhizome with a constriction at the apex, its distally 3-12-lobed middle leaf-segment, and its non-sericeous vestiture. *Geranium crassipes*, as here circumscribed, includes two taxa that Knuth (1912: 87) recognized: his novelty *G.*

*muscoideum* and *G. lechleri*, Weddell's *G. sericeum* var. *microphyllum* elevated to species rank. Knuth (1912: 78) distinguished both taxa on the basis of the length of the leaf indumentum: "brevi subsericeo" in *G. muscoideum* and "satis longa argenteo-lanato-sericea" in *G. lechleri*. Macbride (1949: 513) considered *G. muscoideum* a synonym of *G. crassipes*, but distinguished *G. lechleri* by its "leaves often less deeply 5-parted". I have found a continuous variation in the length of the leaf indumentum, and that the number of leaf segments seems to be a constant five, even in the type material of *G. lechleri*. I therefore subsumed *G. muscoideum* and *G. lechleri* under *G. crassipes*.

**183. *Geranium planum*** Halloy, Brittonia 50: 467, 470 fig. 4. 1998. TYPE LOCALITY: "Argentina. Tucumán: Cumbres Calchaquies, between Cerro Isabel and Cerro Adriana, 4600 m, 5 Mar 1979, S. Halloy 1722 (HOLOTYPE: LIL)". TYPE: Argentina. Tucumán, Cumbres Calchaquies, between Cerro Isabel and Cerro Adriana, 26°36'S, 65°41'W, 5 Mar. 1979, S. Halloy 1722 (holotype, LIL).

*Perennial herbs*, 1-5 cm tall. *Root-stock* 6.8-20 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, without vegetative stems. *Basal leaves* in a persistent rosette; leaf laminas 0.2-0.5(0.6) cm long, 0.3-0.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.75], orbicular in outline, base cordate, not coriaceous, with nerves not projected, sericeous on both surfaces; segments 5, in 1 plane, middle segment broadly lanceolate, 0.4-1.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.27], entire, rarely 2(3)-lobed in distal half; petioles up to 2.1 cm long, without abscission zone, terete, not swol-

len, not deflexed in age, sericeous, with antrorse, appressed, eglandular hairs 0.2-0.3 mm long; stipules 1.2-5 mm long, 0.3-2 mm wide, lanceolate, free, papery, brownish red, sericeous on both surfaces. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.9-1.5]; peduncles 2-6.8

mm long, sericeous, with antrorse, appressed, eglandular hairs 0.1-0.4 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 4-4.9 mm long, 1.7-2.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro absent, sericeous with erect-patent, eglandular hairs 0.2-0.3 mm long on the

abaxial surface and margin, glabrous adaxially. *Petals* 6-7 mm long, 2.8-3.3 mm wide, erect-patent, rounded, white. *Stamens* 10, both whorls bearing anthers; filaments 2.9-3.5 mm long, lanceolate with an abruptly narrowed apex, yellow, with eglandular hairs 0.1-0.2 mm long on the abaxial

Fig. 467. Distribution of *Geranium planum*.

surface and margin; anthers ca. 0.5 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* ca. 2.7 mm long, green. *Fruit* 8-8.8 mm long, erect, discharge of seed-ejection type; mericarps 2.2-2.8 mm long, 1-1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.4 mm long; rostrum 3.8-6 mm long, without a narrowed apex, not twisted, sericeous, with antrorse, appressed, eglandular hairs 0.1-0.2 mm long; stigmatic remnants 0.8-0.9 mm long, with 5 glabrous lobes. *Seeds* 1.8-2 mm long, 0.8-1.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 465, 466.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in January.

*Distribution*. This species is endemic to northwestern Argentina (Fig. 467).

*Habitat*. Gently sloping or horizontal ground bordering schistose peaks; ca. 4500 m.

**Additional specimens examined. Argentina.** TUCUMÁN: Huaca Huasi, Cerro Isabel, 26°36'S, 65°41'W, 3 Feb. 2008, *Grau s.n.* (MA); Tafí Viejo, Cumbres Calchaquies, Abra de Piedras Paradas, 26°36'S, 65°41'W, *Halloy 3362* (herb. Halloy); Tafí Viejo, Cumbres Calchaquies, Abra de Piedras Paradas, 26°36'S, 65°41'W, 9 Jan. 2001, *Halloy 4610* (LIL).

*Discussion*. *Geranium planum*, an endemic of northern Argentina, resembles most closely *G. crassipes* among the stemless species from the Andes in its palmatifid, short, sericeous leaves with usually entire segments, but its sepals lack a mucro and the marginal, long, patent hairs seen in *G. crassipes*. According to Halloy (1998), *G. planum* was found within a narrow elevational range bordering the peaks Cerro Adriana and Isabel and in five fragmented populations. I have searched for the holo-

type with the kind help of LIL's curator Dr. Slanis without success; however, I could examine a specimen from the private collection of Dr. Halloy and LIL-605921, both from the type locality. Additionally, Dr. Grau has provided me with a more recent collection from the same locality, which allowed me to emend the original description and drawing of this species, and add some data not indicated in Aedo & al. (2002: 265).

**184. *Geranium digitatum*** R. Knuth, Repert. Spec. Nov. Regni Veg. 28: 1. 1930. TYPE LOCALITY: "Peru: La Oroya, auf Kalkhängen, 3400 m. (Macbride et Featherstone in Exp. under the Capt. Marshall Field Fund a. 1922 n. 940 -- Typus in Herb. Field Museum n. 517468!)" TYPE: Peru. La Oroya, 11°32'S, 75°54'W, 27 May-7 June 1922, *J.F. Macbride & W. Featherstone 940* (holotype, F-517468!; isotypes, G-00365876!, US-00100880 image!, W!).

*Perennial herbs*, 1.5-7 cm tall. *Root-stock* 4-13.6 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, sometimes with short vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.5-1.5 cm long, 0.4-1.4 cm wide, not peltate, digitate (lateral segments upward) [ratio main-sinus length/middle segment length = 0.32-0.73], polygonal to obtriangular in outline, base cuneate, not coriaceous, with nerves not projected, sericeous on both surfaces; segments 3-5, in 1 plane, middle segment lanceolate, 1.4-3 mm wide at the base [ratio segment width at the base/middle segment length = 0.20-0.25], entire; petioles up to 6.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, sericeous, with patent to retrorse, eglandular hairs 0.3-0.5 mm long; stipules 8.5-12 mm long, 1.5-2.2 mm wide, lanceolate, free, papery, brownish red, sericeous on abaxial surface and

on the margin, glabrous adaxially. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.7-0.8]; peduncles (4)10-67 mm long, sericeous, with patent to retrorse, eglandular hairs 0.3-0.5 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 6.5-9.8 mm long, 2.2-3.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.1-0.4 mm long [ratio mucro length/sepal length = 0.01-0.07], sericeous with erect-patent, eglandular hairs 0.3-0.5 mm long on the abaxial surface and margin, glabrous adaxially. *Petals* 11.1-17 mm long, 5-8 mm wide, erect-patent, rounded, without claw, white, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.2-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.5-5.2 mm long, lanceolate, yellow, with eglandular hairs 0.3-0.5 mm long on the abaxial surface and margin; anthers 1-1.2 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 5.2-6 mm long, yellow. *Fruit* 14-18.5 mm long, erect, discharge of seed-ejection type; mericarps 3-3.2 mm long, 1.5-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.2-0.3 mm long; rostrum 10-12 mm long, with a narrowed apex 1.6-2 mm long, not twisted, sericeous, with erect-patent, eglandular hairs 0.2-0.4 mm long; stigmatic remnants 2.5-3 mm long, with 5 hairy lobes. *Seeds* 2.5-2.9 mm long, 1.4-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 468.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from November to June.

*Distribution*. This species is endemic to central Peru (Fig. 469).

*Habitat*. Arid undisturbed and grazed grassland, in crevices on limestone; 3000-4500 m.

**Additional specimens examined. Peru.** Pérou, 1839-1840, Gay 1208 (P). JUNÍN: Tarma, slopes and bottom of draw of Quebrada Jajaluli, Hacienda Casa Blanca, ca. 18 km SSE of Tarma, 11°25'S, 75°44'W, 27 Nov. 1962, *Ilitis & al.* 107 (BH, MO, US, USM); Tarma, Incatacuna, entre Tarmatambo y Acolla, 11°26'S, 75°42'W, 29 June 1954, *Tovar* 2332 (USM); Jauja, Tarma-Jauja road, 28 km from Tarma, 11°35'S, 75°38'W, 10 Jan. 1984, *Smith* 5687 (MO, NY, TEX, USM); 3 km before highest point Tarma-Acolla-Jauja road, 11°40'S, 75°35'W,

31 Dec. 1961, *Saunders* 710 (BH, K); Yauli, 11°42'S, 75°26'W, 25 May 1922, *Macbride & Featherstone* 940b (W).

**Discussion.** *Geranium digitatum* is easily separated from other sericeous and stemless species from the Andes by its digitate leaves with entire segments. In the type material leaves with five segments are predominant, while in other collections almost all

Fig. 469. Distribution of *Geranium digitatum*.

Fig. 468. *Geranium digitatum*. a. Fruiting branch. b-d. Leaves. e. Peduncle. f. Flower. g. Sepal. h. Petal, abaxial side. i. Staminal filament. j. Fruit. k. Mericarp. l. Seed. (Based on: a, d, g, i-l, *Ilitis & al.* 107, MO; b, c, *Macbride & Featherstone* 940b; e, f, h, *Saunders* 710, K).

leaves have three segments. Some variation is also evident in the indumentum of the nectaries: most of the specimens have a tuft of hairs at the apex of each nectary, but in *Smith* 5687 (MO, NY, TEX) only scattered hairs are present. *Geranium digitatum* shares with *G. weddellii* hairy nectaries and a rostrum with a narrowed apex, but the deeply divided short leaves, antrorsely hairy petioles, and glabrous petals are consistently reliable characters that distinguish *G. weddellii* from *G. digitatum*.

**185. *Geranium trujillense*** Aedo, Candollea 66: 436. 2011. TYPE LOCALITY: "PERÚ. La Libertad: de Chugay a Molino Viejo, 7°47'S 77°46'W, 28.VI.2009, Aedo & Zapata 16682 (holo-: MA [788262]; iso-: USM)". TYPE: Peru. La Libertad, de Chugay a Molino Viejo, 7°47'S, 77°46'W, 28 June 2009, C. Aedo & M. Zapata 16682 (holotype, MA-788262!; isotype, USM!).

*Perennial herbs*, 4.5-6.9 cm tall. *Rootstock* 7.7-13.3 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, without vegetative stems. *Basal leaves* in a persistent rosette; leaf laminas 1.2-1.7 cm long, 0.6-1.2 cm wide, not peltate, digitate (lateral segments upward) [ratio

main-sinus length/middle segment length = 0.53-0.70], rhombic in outline, base cuneate, not coriaceous, with nerves not projected, sericeous on both surfaces; segments 5, in 1 plane, middle segment linear-lanceolate, 0.8-1.3(1.5) mm wide at the base [ratio segment width at the base/middle segment length = 0.06-0.09], entire to 3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.07-0.12]; petioles up to 4 cm long, without abscission zone, terete, not swollen, not deflexed in age, sericeous, with antrorse, appressed, eglandular hairs 0.3-0.6 mm long; stipules 8.9-10 mm long, 1-1.6 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.5-0.8]; peduncles 10-34 mm long, sericeous, with antrorse, subappressed, eglandular hairs 0.3-0.8 mm long; bracteoles absent. *Sepals* 6.2-7.3 mm long, 1.4-2.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.6-1.2 mm long [ratio mucro length/sepal length = 0.10-0.17], sericeous with erect-patent, eglandular hairs 0.4-1.5 mm long on the abaxial surface and margin, glabrous adaxially. *Petals* unknown. *Stamens* 10, both whorls bearing anthers; filaments 2.9-4.4 mm long, lanceolate, unknown color, with eglandular hairs 0.2-0.6 mm long on the abaxial surface and margin; anthers unknown. *Nectaries* 5, hemispheric, glabrous. *Fruit* 10.2-14.3 mm long, erect, discharge of seed-ejection type; mericarps 2.2-3.1 mm long, 0.9-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,  $\pm$  appressed, eglandular hairs 0.1-0.4 mm long; rostrum 5.1-7.9 mm long, without a narrowed apex, not twisted, sericeous, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 1.1-2.4 mm long, with 5

hairy lobes. *Seeds* 1.9-2.1 mm long, 1.2-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 470, 471.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in May.

*Distribution*. This species is endemic to La Libertad, in northern Peru (Fig. 472).

*Habitat*. Rocky slopes among grassy cushions and tufts of grass; 3800-4000 m.

*Additional specimens examined*. **Peru**. LA LIBERTAD: de Chugay a Molino Viejo, des-

Fig. 470. *Geranium trujillense*. a. Habit. b, c. Leaves. d. Indumentum of petiole. e. Indumentum of leaf surface. f. Stipules. g. Sepal. h. Staminal filament. i. Fruit. j. Mericarp. k. Seed. (Based on: Aedo & Zapata 16682, MA).

Fig. 471. *Geranium trujillense* (Based on: Aedo & Zapata 16682, MA).

Fig. 472. Distribution of *Geranium trujillense*.

vio a Huagil, 7°47'S, 77°46'W, 4 May 2003, Sagástegui & al. 17208 (HAO); Patáz, Piedra Grande, La Paccha-Chilia, 8°7.20'S, 77°25'W, 9 May 2003, Sagástegui & al. 17337 (HAO).

**Discussion.** *Geranium trujillense* shares with *G. digitatum* digitate, sericeous leaves, but in *G. trujillense* the segments are narrower and more deeply divided. The apex of the mid-

dle segment may be entire or bear 1-2 lateral short lobelets. *Geranium trujillense* has antrorse hairs on the petioles and usually on the peduncles (such hairs are retrorse in *G. digitatum*), hairy stipules (sericeous in *G. digitatum*), a longer sepal mucro, shorter staminal filaments, glabrous nectaries, and also a shorter fruit with the rostrum lacking a narrowed apex and with shorter seeds than in *G. digitatum*. The two species are allopatric and separated by 300 km. *Geranium trujillense* was first discovered in the HAO herbarium, where two collections were kept: Sagástegui & al. 17208 and Sagástegui & al. 17337. A visit to the locality of Sagástegui & al. 17208 yielded additional fruiting material distributed to MA, HAO, and USM. Unfortunately, in 2010 the HAO herbarium was destroyed in a fire, and all specimens of the two Sagástegui collections (some of them with flowers) were lost. At the present the only available material is in fruit, and thus the description lacks information about petals, anthers, and the gynoecium.

**186. *Geranium nivale*** R. Knuth, Bot. Jahrb. Syst. 37: 563. 1906. TYPE LOCALITY: "Peru: zwischen Tarma und La Oroya im Dep. Junin auf Kalkfelsen bei 4000 m (Weberbauer n. 2533!). - Blühend und fruchtend im Februar". TYPE: Peru. Junín, Tarma, La Oroya, 11°32'S, 75°54'W, A. Weberbauer 2533 (lectotype, designated by Aedo & al. 2002: 259, WRS!).

*Perennial herbs*, 1-3 cm tall. *Root-stock* 5-7 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, without vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.9-1.2 cm long, 1.1-1.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.80-0.86], polygonal in outline, base cordate, not coriaceous, with nerves not projected, sericeous on both surfaces; segments 5, in 1 plane, middle segment broadly obovate, 0.7-1.5 mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.15], entire; petioles up to 1.8 cm long, without abscission zone, terete, not swollen, not deflexed in age, sericeous, with patent to retrorse, eglandular hairs 0.2-0.7 mm long; stipules 8-12 mm long, 2 mm wide, lanceolate, free, papery, brownish red, sericeous on abaxial surface and on the margin, glabrous adaxially. Cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.8-0.9]; peduncles 7-22 mm long, sericeous, with patent, eglandular hairs 0.4-0.7 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 6.7-8.2 mm long, 2-3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro ca. 0.2 mm long [ratio mucro length/sepal length = 0.02-0.03], sericeous with erect-patent, eglandular hairs 0.3-0.7 mm long on the abaxial surface and margin, sparsely hairy adaxially. *Petals* 13-18 mm long, 5-5.5 mm wide, erect-patent, rounded, without claw, white, hairy on the base of the abaxial surface, ciliate on

the basal margin, with hairs 0.5-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6-6.5 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.5 mm long on the abaxial surface and margin; anthers ca. 1.1 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* ca. 7 mm long, yellow. *Fruit* 12-13 mm long, erect, discharge of seed-ejection

type; mericarps ca. 2.5 mm long, 1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, sericeous, with erect-patent, eglandular hairs 0.4-0.6 mm long; rostrum 9.5-10 mm long, with a narrowed apex 1.2-1.5 mm long, not twisted, sericeous, with erect-patent, eglan-

dular hairs 0.4-0.6 mm long; stigmatic remnants ca. 1 mm long, with 5 hairy lobes. *Seeds* unknown. Cotyledons not studied. Fig. 473.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to October.

*Distribution*. This species ranges through central Peru (Fig. 474).

*Habitat*. On moist ground in puna; ca. 4000 m.

**Additional specimens examined. Peru.**

APURIMAC: Andahuaylas, 13°40'S, 73°25'W, Feb., *Pearce s.n.* (K). JUNÍN: camino de la Oroya a Tarma, 11°14'S, 75°46'W, 12 Oct. 1863, *Isern 569* (F); bajada del Ricrican camino de la Oroya a Tarma, 11°14'S, 75°46'W, 29 Sep. 1863, *Isern 569b* (F); La Oroya, 11°32'S, 75°54'W, 1919, *Kalenborn & Kalenborn 88* (CAS, NY). LIMA: puna antes de bajar a Pampas, 11°18'S, 76°45'W, Feb. 1863, *Raimondi 47* (P).

*Discussion*. *Geranium nivale* shares with *G. ruizii*, *G. planum*, and *G. crassipes* palmatifid sericeous leaves, but differs from them in the fruit rostrum with a narrowed apex and the longer petals. *Geranium nivale* has longer leaves than *G. ruizii*, with lanceolate entire segments, whereas the leaves of *G. ruizii* have obtriangular segments that are apically 3-lobed. *Geranium planum* and *G. crassipes* also have entire leaf segments [rarely 2(3)-lobed in *G. planum*], but they

Fig. 477. Distribution of *Geranium ruizii*.

*Stamens* 10, both whorls bearing anthers; filaments 3.3-4.7 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.8 mm long on the abaxial surface and margin; anthers 0.8-1 mm long, yellow. Nectaries 5, hemispheric, usually glabrous. *Gynoecium* 3.7-4.5 mm long, yellow. *Fruit* 10-12 mm long, erect, discharge of seed-ejection type; mericarps 2-2.9 mm long, 1-1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal calus, without a basal prong, brown,

with erect-patent, eglandular hairs 0.3-0.6 mm long; rostrum 6-6.9 mm long, without a narrowed apex, not twisted, woolly-sericeous, with patent, eglandular hairs 0.4-1.6 mm long; stigmatic remnants 1-2.4 mm long, with 5 hairy lobes. *Seeds* 1.6-2.1 mm long, 1-1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 475, 476.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217, Bortenschlager 1967: 425).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to June.

*Distribution*. This species ranges from northern and southern Peru to western Bolivia (Fig. 477).

*Habitat*. Among rocks, on exposed grassy slopes, among *Azorella* Lam. cushions in puna; 2700-5000 m.

**Discussion.** *Geranium ruizii* can be distinguished from all other stemless Andean species by its palmatifid, sericeous leaves, with the middle and usually also the lateral segments 3-lobed. It also has sericeous petioles with patent to antrorse hairs. Knuth (1912: 78) differentiated *G. dielsianum* from *G. ruizii* on the basis of leaf size (longer in *G. dielsianum*) and Macbride (1949: 513) by the "lateral as middle

leaf-divisions mostly or all 3-dentate" against "lateral leaf-divisions often entire or 1-dentate" in *G. ruizii*. I have found a continuous variation in leaf size, and that entire lateral segments occur sporadically, often among specimens with 3-lobed lateral segments, which indicate that there is no basis for recognizing *G. dielsianum* as distinct from *G. ruizii*. In a collection from Peru (*Sánchez & Cabanillas* 6735, F, MA) the nectaries have some hairs at the apex but otherwise match *G. ruizii*, which usually has glabrous nectaries. Most of the records of *G. ruizii* are from northern and central Peru. One isolated locality, in Bolivia near the Peruvian border (*Menhofer* 1795, MA), points up the insufficiency of collecting in the intervening region. More puzzling is a record of *G. ruizii* in Colombia. A specimen at K (*Lobb* 285) is labeled as "Columbia." According to Chaudhri & al. (1972: 454), William Lobb collected in southern Colombia (mainly in Nariño), an area in which the presence of *G. ruizii* is plausible; however, no other collection of *G. ruizii* from Colombia and Ecuador was found in any herbarium. According to the former curator of COL J.L. Fernández Alonso (*in litt.*) some other Lobb collections are similarly problematic.

**188. *Geranium sericeum* Willd.** ex Spreng., Syst. Veg. 3: 70. 1826. TYPE LOCALITY: "sericeum W. herb. ... Amer. austr.? Humb.". TYPE: Ecuador, Antisana, 0°30'S, 78°10'W, A. Bonpland & F.A. Humboldt s.n. (lectotype, designated by Aedo & al. 2002: 271, B-W-12529-01-0 image!; isolectotypes, BH-fragment!, HAL!, P-00136928!, PR-616138 fragment!).

*Perennial herbs*, 2-4.1 cm tall. *Root-stock* 6-14 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* scapiform, cushion-like, stolons absent, without vegetative stems. *Basal leaves* in a persistent rosette; leaf laminae 0.9-1.7 cm long, 1.1-1.7 cm wide, not

peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, sericeous on both surfaces; segments 7, in more than 1 plane, middle segment obtriangular (with linear-lanceolate lobes), 0.3-0.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.05-0.09], 3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.51-0.89]; petioles up to 3 cm long, without abscission zone, terete, not swollen, not deflexed in age, woolly-sericeous, with patent to retrorse (not appressed), eglandular hairs 0.8-1.6 mm long; stipules 12-18 mm long, 1.1-3.9 mm wide, lanceolate, free, papery, brownish red, sericeous on abaxial surface and on the margin, glabrous adaxially. *Cymules* 1-flowered, solitary [ratio cymule length/leaf length = 0.4-0.9]; peduncles 1-8.1 mm long, woolly-sericeous, with patent, eglandular hairs 0.8-1 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 7-9 mm long, 1.8-2.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.8 mm long [ratio mucro length/sepal length = 0.05-0.11], woolly-sericeous, with antrorse, eglandular hairs 1-2 mm long on the abaxial surface and margin, ± hairy adaxially. *Petals* 9-11.4 mm long, 3.7-6 mm wide, erect-patent, rounded, without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.6-4.5 mm long, lanceolate, white, with eglandular hairs 0.5-0.8 mm long on the abaxial surface and margin; anthers 1-1.2 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4-4.3 mm long, yellow. *Fruit* 10.9-14.5 mm long, erect, discharge of seed-ejection type; mericarps 2.5-3.5 mm long, 1.2-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, woolly-sericeous, with erect-patent, eglandular hairs 0.7-1.5

mm long; rostrum 6.8-10 mm long, without a narrowed apex, not twisted, woolly-sericeous, with patent, eglandular hairs 0.3-1.4 mm long; stigmatic remnants 0.8-2.3 mm long, with 5 usually glabrous lobes. *Seeds* 1.7-2.2 mm long, 1-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 478, 479.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217; Bortenschlager 1967: 425).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species is endemic to central Ecuador (Fig. 480).

*Habitat*. Grass tussocks in paramo, open sandy areas, ravines and rock outcrops; 3900-4900 m.

*Additional specimens examined*. **Ecuador**. *Discussion*. *Geranium sericeum*, an endemic of Ecuador, is known only from a small area near the Volcán Antisana. It is easily distinguished from other palmatisect-leaved species within its range by the presence of a woolly-sericeous indumentum on

the laminas, petioles, peduncles, sepals, and fruits. According to Fryxell (1991), *Sida radiculiflora* C. Presl (Malvaceae) should be considered a synonym of *G. sericeum*. Fryxell stated that Presl (1831-1835) described his *Sida radiculiflora* from Mt. Chimborazo, Ecuador, but no original specimen was kept at PR. Thus, Fryxell (1991)

designated a collection by Née (MA-252584) as neotype of *S. radiculiflora*, which is (in his view) *G. sericeum*; however, some recent information contradicts Fryxell's interpretation of *S. radiculiflora*. Presl (1835: 106) described *S. radiculiflora* from Guayaquil, not from Chimborazo, and, according to Halfdan-Nielsen (unpubl.),

Fig. 478. *Geranium sericeum*. a. Fruiting branch. b, j. Leaves. c. Flower. d. Sepal. e. Petal. f. Staminal filament. g. Fruit. h. Mericarp. i. Seed. (Based on: a, c, *Black* 178, AAU; b, d-j, *Løjtnant & Molau* 15325, AAU).

Fig. 479. *Geranium sericeum* (Based on: a-d, Aedo & León 13351, MA; e, without voucher, from Cerro Antisana, Ecuador, photo: C. Ulloa).

Fig. 480. Distribution of *Geranium sericeum*.

there exists a specimen collected by Haenke from Guayaquil, which is *Sida* and presumably the type of *S. radciflora* (PR-185995-591). Also, examination of Née's collection (MA-252584) reveals that this is *Geranium ecuadoriense* rather than *G. sericeum* (Aedo & al. 2002: 271).

**189. *Geranium tovarii*** Aedo, *Anales Jard. Bot. Madrid* 58: 184. 2000. TYPE LOCALITY: "Perú. *Discussion*. *Geranium tovarii*, a rare endemic from central Peru, resembles

most closely *G. weddellii*, from which it is easily differentiated by its much shorter petals, longer hairs on the margin of the sepals, glabrous nectaries, and a fruit without a narrowed apex. The ranges of *G. tovarii* and *G. weddellii* are completely allopatric.

**190. *Geranium weddellii*** Briq., Annuaire Conserv. Jard. Bot. Genève 11/12: 183. 1908. **Discussion.** *Geranium weddellii* is easily recognized among other sim-

ilar sympatric species by its small and palmatisect, sericeous leaves and its sericeous petioles with antrorse, appressed hairs. The differences between *G. weddellii* and *G. tovarii* are addressed under the latter species.

**The Diffusum Group**—This group is characterized by its prostrate or ascending habit, its opposite leaves and its 1-flowered cymules arranged in a monochasial inflorescence. The cymules usually lack pedicels. The leaves are usually palmatifid, polygonal in outline, and with few but deep lobes. The petals are of small size and the fruit rostrums usually lack a narrowed apex.

*Perennial herbs*, 4-53 cm tall. *Root-stock* 2.4-11.9 mm in diameter,  $\pm$  vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* prostrate to ascending, leafy, sometimes rooting at nodes, stolons absent, without vegetative stems, with  $\pm$  retrorse, appressed, eglandular hairs 0.2-0.6 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae 0.7-2.4 cm long, 0.6-2.6 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.75)0.83-0.89(0.90)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtrian-gular (with lanceolate lateral lobes joined to the middle one), 0.5-2.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.06-0.32], (1)3(5)-lobed at the apex [ratio secondary sinus length/middle

segment length = 0.31-0.50]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse (rarely antrorse), appressed, eglandular hairs 0.1-0.7 mm long; stipules 2.3-9.5 mm long, 0.7-1.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, minutely hairy adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.6)1-2.1(3.3)]; peduncles 5.3-62 mm long, with retrorse (rarely antrorse), appressed, eglandular hairs 0.2-0.6 mm long; bracteoles. Flowers actinomorphic. *Sepals* 3.4-8 mm long, 1.3-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-1.1 mm long [ratio mucro length/sepal length = 0.06-0.2], with erect-patent, eglandular hairs 0.3-1.5 mm long on the abaxial surface, minutely hairy adaxially. *Petals* (4.2)4.9-8.2(12.4) mm long, 1.7-5.7 mm wide, erect-patent, rounded, without claw, white or purple, glabrous or ciliate on the basal margin, with hairs 0.1-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.1-4.8 mm long, lanceolate, white or yellow, with eglandular hairs 0.1-0.5 mm long on the abaxial surface and margin; anthers 0.4-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.4-5.3 mm long, yellow. *Fruit* 8.3-16 mm long, erect, discharge of seed-ejection type; mericarps 1.8-3.8 mm long, 0.9-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.6 mm long; rostrum 4.8-10.5 mm long, usually without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.7 mm long; stigmatic remnants 0.5-2 mm long, with 5 glabrous lobes. *Seeds* 1.4-2.9 mm long, 0.9-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 486, 487.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 433 [sub *G. sodiroanum*]).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from Venezuela to Colombia, Ecuador, and northern Peru (Fig. 488).

*Habitat*. Roadsides, rocky or wet areas, grassy fields, grassy tussock paramos, disturbed and grazed shrublands; 1600-4600 m.

*Representative specimens examined*.

Fig. 486. *Geranium diffusum*. a. Habit. b, c. Leaves, adaxial side. d. Leaf, abaxial side. e. Bracteoles. f. Pedicel. g. Flower, sepals and petals removed. h. Sepal. i. Petal. j. Staminal filament. k. Fruit. l. Mericarp. m. Seed. (Based on: a, d-m, Aedo & Ulloa 12916, MA; b, Sparre 13761, AAU; c, Catalán & al. s.n., MA-709663; e, Halfdan-Nielsen & León 60, C).

**Discussion.** *Geranium diffusum* has a prostrate to ascending habit with small leaves and 1-flowered cymules. Well-developed plants sometimes root at the nodes. This species grows in a broad latitudinal range across

Fig. 487. *Geranium diffusum* (Based on: a, Aedo & Ulloa 12902, MA; b-d, Aedo & Leiva 16448, MA; e, Grande & Aedo 2515, MA).

Fig. 488. Distribution of *Geranium diffusum*.

the northern Andes and shows some variability. The leaves usually have an obtriangular and 3-lobed middle segment, although leaves with 1-lobed segments rarely present. Such specimens resemble *G. sibbaldioides* subsp. *sibbaldioides*, but the leaves are covered with appressed hairs on both surfaces and lack a bristle at the tip of the lobes, and their young stems are not hidden by old stipules. *Geranium diffusum* usually has leaves with appressed eglandular hairs on both surfaces; the indumentum varies in density, and some unusual specimens are almost hoary-white. The cymules usually lack pedicels and bracteoles, although occasionally, cymules with a peduncle, two bracteoles, and a pedicel are present. In these rare cases, most of the cymules of the plant are without pedicel and bracteoles. The rostrum of the fruit usually ends abruptly without a narrowed apex, although some specimens have a rostrum with a short narrowed apex.

The type of *G. harmsii* agrees in most characters with *G. diffusum*, although it shows unusually long ped-

icels. Such long pedicels have also been found in plants from central Ecuador. The type lacks fruits and well-developed basal leaves; it is here assigned to *G. diffusum*. There is a surprising gap of ca. 400 km between the southern populations of *G. diffusum* in northern Peru and the type locality of *G. harmsii* in central Peru. Another species quite similar to *G. diffusum* is *G. smithianum*, which differs in the 5-lobed middle segment of the leaf and is known from scattered localities in central and southern Peru. Perhaps additional collections from the type locality of *G. harmsii* may reveal whether this variant indeed represents *G. diffusum* or only a form of *G. smithianum*. If the latter, then the name *G. harmsii* has priority over *G. smithianum*. In the protologue of *G. diffusum*, Kunth noted "Crescit in montibus Peruviae" (Humboldt & al. 1822: 230); however, in the Bonpland herbarium at P, "Perou (Quindiu)" is indicated on the label and later the word "Perou" was corrected by "Ne Grenade." The locality given in the protologue may be in error; Quindio

(Colombia) is a well-known locality visited by Humboldt and Bonpland (Stearn 1968: 110). Yet, the collection for *G. diffusum* at B is heterogeneous and includes a sheet (B-W-12535-02-0) belonging to *G. diffusum* and another other sheet (B-W-12535-01-0) that is *G. reptans*. The same is true for the duplicates at P: one sheet (numbered as 136924) of *G. diffusum* and another specimen (numbered as 136923) with patent hairs on petioles and pedicels, which is *G. reptans*. Both sheets of *G. reptans* are to be excluded of the type gathering of *G. diffusum*.

Knuth (1912: 211) based *G. imbaburae* on two collections by Stuebel (52 and 67a); no specimens of these collections have been located. A photograph of Stuebel 52 at F, GH, and MO shows a specimen that well matches *G. diffusum* in leaf shape, the 1-flowered cymules, and indumentum. *Geranium sodiroanum* is here listed as a synonym of *G. diffusum*, because the original description of *G. sodiroanum*,

especially noting 1-flowered cymules and pedicels with retrorse and appressed hairs, agrees with it. Both syntypes, *Sodi* 213 and *Weberbauer* 255, are lost, and no duplicates were found. A special search of Sodi's specimen at QPLS and of Weberbauer's specimen at MOL and USM was conducted without success. Knuth (1912: 212) erroneously attributed the type locality of *G. columbianum* to Colombia; however, Moritz collected near Mérida in Venezuela. Knuth (1912: 212) listed two syntypes, of which I selected *Moritz* 1246 as lectotype, because *Moritz* 1245 is only a small fragment with some 2-flowered cymules. This character is exceptional in *G. diffusum*. *Geranium robustipes* was described by Knuth (1938: 62) also from a locality near Mérida. Unfortunately, the type was destroyed and no duplicate has been found. Yet, the original description provides details of indumentum, and inflorescence and leaf shape, which strongly indicate that *G. robustipes* is a synonym of *G. diffusum*. The names *G. chimborazense* and *G. holm-nielsenii* are also listed as synonyms of *G. diffusum*. The lectotype chosen for *G. chimborazense*, *Meyer* 181 (JE), has antrorse hairs on the pedicels and petioles. This characteristic was also mentioned by Halfdan-Nielsen (1996: 272), when she described her *G. holm-nielsenii*; she also considered the congested habit as a defining character. I sampled several populations of *G. diffusum* (*Aedo* 13224, 13225, 13235) on the slopes of the Chimborazo volcano and found plants with different combinations of these characters. In exposed habitats plants of *G. diffusum* resemble small cushions, because they have very short branches. Yet, in the same area in sheltered places, such as under shrubs, plants of *G. diffusum* have long branches and assume the usual spreading habit. The type collection of *G. soratae*, *Rusby* 763, is a mixed gathering; the sheet at MO is *G. diffusum*. This specimen has not been mapped because it may be a labelling mistake.

### 192. *Geranium pseudodiffusum*

*Aedo*, Syst. Bot. 35: 168, 169 fig. 1. 2010. TYPE LOCALITY: "Ecuador. Azuay, páramo de Cajas, Chuspipuña, 20 July 2006, *Aedo* & *Ulloa* 13101 (holotype, MA!; isotypes, MO!, QCNE!)". TYPE: Ecuador. Azuay, Páramo de Cajas, Chuspipuña, 2°48'N, 79°13'W, 20 July 2006, *C. Aedo* & *C. Ulloa* 13101 (holotype, MA-745449!; isotypes, HA-211881!, JE-00012293!, MO-2071647!, QCNE-259!).

*Perennial herbs*, 3-17 cm tall. *Root-stock* 1-11 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, sometimes rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-1.5 mm long and patent, glandular hairs 0.2-0.5 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae 0.5-2.9 cm long, 0.7-2.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.74)0.88-0.91(0.98)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs and scattered, patent glandular hairs on margin and on nerves of the abaxial surface (sometimes also on adaxial nerves); segments 5, in 1 plane, middle segment obtriangular (with lanceolate lateral lobes joined to the middle one), 0.5-1.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.07-0.20], 3(5)-lobed at the apex [ratio secondary sinus length/middle segment length = (0.31)0.44-0.52(0.61)]; petioles up to 17 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.3-0.7 mm long and patent, glandular hairs 0.2-0.5 mm long; stipules 2.8-6.8 mm long, 1-1.8 mm wide, lanceolate, free, papery, brownish red, with scattered, eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme;

cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.2-0.8(1.1)]; peduncles 2.3-20.5 mm long, with retrorse, appressed, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.2-0.6 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 3.9-5.7 mm long, 1-2.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.8 mm long [ratio mucro length/sepal length = 0.09-0.17], with erect-patent, eglandular hairs 0.2-0.7 mm long and glandular hairs 0.2-0.4 mm long on the abaxial surface, minutely hairy adaxially. *Petals* 4.8-7.1 mm long, 1.2-2.2 mm wide, erect-patent, rounded, without claw, white or pale pink, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 2.1-3 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 0.4-0.7 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.4-3.2 mm long, yellow. *Fruit* 6.4-11.2 mm long, erect, discharge of seed-ejection type; mericarps 1.8-2.6 mm long, 0.8-1.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.5 mm long and sometimes glandular hairs 0.1-0.4 mm long; rostrum 3.9-6.6 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long and, sometimes, glandular hairs 0.1-0.4 mm long; stigmatic remnants 0.8-1.2 mm long, with 5 glabrous lobes. *Seeds* 1.3-1.8 mm long, 0.7-1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 489, 490.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to December.

*Distribution*. This species ranges from Ecuador to northern Peru (Fig. 491).

*Habitat*. Bogs and very humid habitats in *Polylepis* Ruiz & Pav. forests and open grassy areas; 3300-4150 m.

**Additional specimens examined.** **Ecuador.** AZUAY: Páramo de Cajas, Laguna Toreadora, 2°46'S, 79°13'W, 20 July 2006, *Aedo & Ulloa* 13105 (MA); Páramo de Cajas, Laguna Toreadora, 2°47'S, 79°13'W, 20 Nov. 1991, *Halfdan-Nielsen* 51bis (C); Páramo de Cajas, 20 km de Cuenca, 2°48'S, 79°9'W, 19 Nov. 1991, *Halfdan-Nielsen* 45 (C); Páramo de Cajas, 18 km de Cuenca, 2°51'S, 79°8'W, 19 Nov. 1991, *Halfdan-Nielsen* 43 (C). **Discussion.** *Geranium pseudodiffusum*, as the epithet implies, resembles *G. diffusum* in general appearance. The leaves of *G. diffusum* are ± densely covered with small and appressed hairs on both surfaces, whereas in *G. pseudodiffusum* the hairs are restricted to the margin and the nerves of the abaxial surface, and more rarely on the nerves of the adaxial surface. Additionally, *G. pseudodiffusum* has

glandular hairs on stems, pedicels, sepals, petioles, and sometimes on the leaf lamina (especially towards the base). Glandular hairs are also often present on mericarps and the rostrum of the fruit. *Geranium antisanae* also has a glandular indumentum, but it is easily distinguished from *G. pseudodiffusum* by its less deeply di-

vided leaves, which are densely covered by glandular and eglandular patent hairs (see that species). *Geranium pseudodiffusum* differs from *G. diffusum* also in some minor quantitative features, although with some overlap. The leaves of *G. pseudodiffusum* are more deeply divided, i.e., the segments as well as the apical lobes

Fig. 489. *Geranium pseudodiffusum*. a. Habit. b. Leaf, adaxial side. c. Leaf, abaxial side. d. Bracteoles. e. Pedicel. f. Flower, sepals and petals removed. g. Sepal. h. Petal. i. Staminal filament. j. Fruit. k. Mericarp. l. Seed. (Based on: *Aedo & Ulloa* 13101, MA).

Fig. 490. *Geranium pseudodiffusum* (Based on: a, b, Aedo & Ulloa 13101, MA; c, d, Aedo 16494, MA).

are longer, than leaves of *G. diffusum*. The peduncles are shorter than in *G. diffusum*, and thus cymules appear shorter than the adjacent leaf. Petals are shorter and narrower than in *G. diffusum* and always glabrous, and staminal filaments and fruits are also shorter. *Geranium pseudodiffusum* is confined to paramos of central Ecuador and northern Peru, where *G. dif-*

*fusum* is also found. I collected both species at several localities where they grew together; I found *G. diffusum* in disturbed areas, whereas *G. pseudodiffusum* occurs in peat bogs or very humid habitats. Rarely, *G. diffusum* may grow at the edges of peat bogs or even on tussocks of grasses, but *G. pseudodiffusum* is restricted to the swampy base of such tussocks.

Fig. 491. Distribution of *Geranium pseudodiffusum*.

**193. *Geranium antisanae*** R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 215. 1912. TYPE LOCALITY: "Ecuador: Antisana, 4056 m (Stuebel, Fl. Aequat. a. 1871 n. 185n -- Typus in Herb. Berlin!).-- Blühend Oktober". TYPE: Ecuador. Napo, Antisana, 0°28'S, 78°08'W, 1871, A. Stuebel 185n (holotype, B destroyed). Ecuador. Pichincha, Peñas Blancas, 0°18'S, 78°14'W, 14 July 2006, C. Aedo & C. Ulloa 12946 (neotype, designated by Aedo 2012: 275, MA-744854!; isoneotypes, MO!, QCNE!).

*Perennial herbs*, 2.8-11 cm tall. *Rootstock* 3.3-7.1 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* prostrate, leafy, sometimes rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.3-0.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas 0.8-1.3 cm long, 0.9-1.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.64)0.68-0.77(0.81)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± patent, eglandular and glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular (with lanceolate lateral lobes joined to the middle one), 1.5-2.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.22-0.45], (1)3-lobed at the apex [ratio secondary sinus length/middle segment length = (0.20)0.25-0.31(0.36)]; petioles up to 4.8 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.4-0.7 mm long; stipules 1.9-6 mm long, 1.2-1.8 mm wide, lanceolate to broadly lanceolate, free, papery, brownish red, with eglandular and glandular hairs on abaxial surface and on the margin, minutely hairy adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 0.4-1.3]; peduncles 6.3-14.6 mm long, with patent, eglandular hairs 0.1-0.6 mm long and patent, glandular hairs 0.2-0.5 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 3.7-5 mm long, 1.7-2.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.4 mm long [ratio mucro length/sepal length = 0.05-0.10], with erect-patent, eglandular hairs 0.5-1.2 mm long and patent, glandular hairs 0.2-0.4 mm long on the abaxial surface, minutely hairy adaxially. *Petals* 6.6-8.2 mm long, 1.7-3.1 mm wide, erect-patent, rounded, without claw, white, glabrous.

*Stamens* 10, both whorls bearing anthers; filaments 2.1-3.2 mm long, lanceolate, white, with eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 0.6-0.8 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.9-3.3 mm long, yellow. *Fruit* 9.4-10.9 mm long, erect, discharge of seed-ejection type;

mericarps 1.9-2.5 mm long, 1.1-1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-0.4 mm long and sometimes, patent glandular hairs 0.3-0.4 mm long; rostrum 5.4-6.7 mm long, without a narrowed

apex, not twisted, with erect-patent, eglandular hairs 0.1-0.6 mm long and patent, glandular hairs 0.2-0.5 mm long; stigmatic remnants 0.9-1.5 mm long, with 5 glabrous lobes. *Seeds* 1.4-1.9 mm long, 0.8-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 492, 493.

Fig. 493. *Geranium antisanae* (Based on: Aedo & Ulloa 12946, MA).

Fig. 494. Distribution of *Geranium antisanae*.

*Pollen.* Ornamentation not studied.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from July to August.

*Distribution.* This species is endemic to northern Ecuador (Fig. 494).

*Habitat.* Among large grass tussocks or cushions of *Azorella* Lam., and at edge of *Polylepis* Ruiz & Pav. forests; 3750-4200 m.

*Additional specimens examined. Ecuador.* COTOPAXI: falda W del Cerro Antisana, origen del río Antisana, 0°28'S, 78°12'W, Jan. 1983, *Balslev & al.* 3961 (QCA); besides road leading to Quito from Hacienda Antisana, 0°30'S, 78°12'W, 26 July 1960, *Grubb & al.* 623 (NY); ladera N del volcán Cotopaxi, pr. Ingapirca, 0°35'S, 78°26'W, 1 Aug. 2006, *Aedo* 13342 (MA); volcán Cotopaxi, N slope on the left side of the road to the refuge, 0°39'S, 78°26'W, 19 July 1995, *Sklenář & Kosteckova* 85-5 (AAU). NAPO: Pintag, ladera SW del volcán Antisana, 0°29'S, 78°12'W, 3 Aug. 2006, *Aedo* 13350 (MA). PICHINCHA: Chaupi, ladera NE de los volcanes Ilinizas, 0°37'S, 78°41'W, 2 Aug. 2006, *Aedo* 13347 (MA).

*Discussion.* *Geranium antisanae* shares a glandular indumentum with *G. pseudodiffusum* but differs greatly in leaf shape and leaf indumentum. The middle leaf segment of *G. antisanae* has a broader base and is shorter than in *G. pseudodiffusum*. The secondary divisions, i.e., the lobes of the middle segment, are also shallower in *G. antisanae* than in *G. pseudodiffusum*. The middle leaf segment is usually 3-lobed in *G. antisanae*, although some leaves with undivided segments can be found occasionally towards the base of the plant. Leaves of *G. antisanae* are covered with short, weak, dense, patent, glandular, and eglandular hairs on both surfaces. In *G. pseudodiffusum* the leaves bear appressed eglandular hairs restricted to margins and nerves (mainly abaxially); sometimes, some glandular patent hairs arise from the nerves towards the base of the leaf. *Geranium antisanae* differs also in some minor quantitative features with some overlap. The sepal mucro of *G. antisanae* is shorter than that of *G. pseudodiffusum*, and the petals are longer.

Because the holotype *G. antisanae* is no longer extant, a neotype was designated (Aedo 2012: 275), which was collected about 20 km northwest of the Antisana massif, the original type locality of this species. The photograph of the lost holotype (at F, G, GH, NY) shows a fragment that well matches the neotype collection.

**194. *Geranium ayavacense*** Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 5: 231. 1822, ["ayavacense"]. TYPE LOCALITY: "Crescit prope Ayavaca Peruvianorum, alt. 1400 hex.". TYPE: Peru. Piura. **Discussion.** *Geranium ayavacense* is well characterized by its palmatisect leaves in which the segments are greatly narrowed at the base. The rhombic middle segments have nar-

row lateral lobes, separated by deep sinuses, that diverge from the central lobe. *Geranium ayavacense* shares retrorse appressed eglandular hairs on petioles and pedicels with *G. diffusum*. Some specimens of *G. diffusum* with deeply palmatifid leaves are difficult to differentiate from *G. ayavacense*; however, in *G. diffusum* lateral lobes of the middle segment are straight (not curved backwards and divergent) and less deeply divided than in *G. ayavacense*. The middle segment of a leaf of *G. ayavacense* usually has three lobes, although occasionally leaves with 4-lobed segments can be found. Some herbarium specimens have many leaves with undivided segments (e.g., Cajamarca, *Campos* 5019, USM; Piura, *Cano* 1481, USM); these are included in *G. ayavacense*, because the leaves are palmatisect and occasionally have some segments with 2-3 divergent lobes. I studied this variation in a population in Piura (*Aedo* 16622, MA) and found individuals with undivided segments intermingled with others that had 3-lobed segments. These observations indicate such variability is an occasional and local phenomenon, which does not merit taxonomic recognition.

In the protologue, the specific epithet was given as "agavacense" (Humboldt & al. 1822), which is probably a misprint. Steudel (1840) rightly corrected the specific epithet to "ayavacense" to indicate the type locality, Ayavaca. There is some controversy concerning orthography of the name for this village, which some authors write as "Ayabaca"; at least eight specific epithets have been proposed with "b." Apparently, Ayavaca is derived from Ayahuaca (a pre-Incan people in northern Peru). The Quechua diphthongs "ua" and "ui" preceded by an "h" should be transliterated to Latin or Spanish as "v." The holotype of *G. piurense* is lost, and no duplicates have been located. Knuth's (1922) detailed description agrees very well with *G. ayavacense*, and both names were based on col-

lections from the same locality. Macbride (1949: 514, 530) was the first author to cite *G. piurense* as a synonym of *G. ayavacense*. A specimen of *G. ayavacense* at BM, labeled as "Peruvia. 18.. Mathews", most likely is an isoelectotype of *G. mathewsii*. *Geranium ayavacense* was reported from Venezuela by Knuth (1912: 213) based on *Linden 432* (Gl, Pl), which is *G. diffusum*.

JUNÍN: Chanchamayo, 11°3'S, 75°19'W, 12 Oct. 1863, Isern 2178 (F, MA).

*Discussion*. *Geranium smithianum* resembles *G. diffusum* in general appearance and shares with it an indumentum of appressed, retrorse eglandular hairs on stems, petioles, and pedicels. The most consistent difference is leaf shape. In *G. smithianum* the middle segment is rhombic and 5(6)-lobed, whereas in *G. diffusum* it is obtriangular and usually 3-lobed.

Some specimens of *G. smithianum* have leaves with 3-lobed middle segments towards the apex of the inflorescence, although most of the leaves are 5-lobed. The two species are also allopatric. *Geranium diffusum* is found from Venezuela to northern Peru, whereas *G. smithianum* is restricted to central and southern Peru. Some poorly prepared specimens of the sympatric *G. ayacuchense* may be confused with *G. smithianum*; however, *G. ayacuchense* is easily distinguished by its longer petals with a well-differentiated claw and by its fruit with a rostrum narrowed at the apex. A collection from central Peru on which *G. harmsii* is based, may be a variant of *G. smithianum* or *G. diffusum*; see the discussion of *G. diffusum*.

**Discussion.** *Geranium reptans* shares with *G. diffusum* a prostrate to ascending habit; well-developed plants sometimes root at the nodes. The leaves are also similar and usually have 3-lobed middle segments; however, in *G. reptans* the indumentum is denser, and the hairs are longer than in *G. diffusum*. The most consistent and diagnostic character for *G. reptans* is the presence of patent, eglandular hairs on pedicels and petioles. *Geranium reptans* occurs from central Colombia to Ecuador (one collection is recorded from northern Peru near the border with Ecuador) and is thus sympatric with *G. diffusum* in the central to southern part of its range. In this region, both species share the same disturbed habitats and sometimes are difficult to differentiate. Two specimens with glandular hairs on stem, petioles, and pedicels have been found in Nariño, Colombia: Stancik 2615, COL; A. Fernández & L. E. Mora 1122, COL, NY. They agree well with *G. reptans* otherwise, especially in leaf shape and indumentum, which avoids any confusion with *G. pseudo-diffusum* or *G. antisanae*. Populations of *G. reptans* from southern Colombia need further study to assess the extent of variability. The holotype of *G. reptans* was destroyed, and no duplicates of Sodiro 211 were found in major herbaria nor Sodiro's herbarium at QPLS. Consequently a neotype was designated (Aedo 2012: 284), which was collected in the same region as the holotype. It well matches with the photograph of the lost holotype (at F, GH, NY) and the original description.

**The Renifolium Group**—This group is characterized by its prostrate or ascending habit, its opposite leaves and its 1-flowered cymules arranged in a monochasial inflorescence. Except in *G. stuebelii*, the cymules lack pedicels. The leaves are palmatifid, usually orbicular in outline, and with few and shallow teeth towards the apex of the segments. The petals are of medium size.

**197. *Geranium renifolium*** Hieron., Bot. Jahrb. Syst. 21: 315. 1895. TYPE LOCALITY: "Peruvia: crescit supra Tambo Mayo inter Pacasmayo et Moyobamba, mense Aprili-Junio florens (coll. peruv. n. 43)". TYPE: Peru. Cajamarca, supra Tambo Mayo inter Pacasmayo et Moyobamba, 7°05'S, 78°18'W, A. Stuebel 43 (lectotype, designated by Knuth, 1912: 159, B destroyed). Peru. La Libertad, Sánchez Carrión, Comumbamba, subiendo al nevado Huaylillas, 7°52'S, 78°01'W, 20 May 2001, A. Sagástegui & M. Zapata 16461 (neotype, designated by Aedo 2012: 289, MA-658509!; isoneotype, F).

*Perennial herbs*, 9-27 cm tall. *Rootstock* 4.1-12.3 mm in diameter, ± vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas 0.8-1.9(3) cm long, 1.2-2(3.5) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.53-0.67], orbicular in outline, base cordate, not coriaceous, with nerves not projected, glabrous except on margin and nerves of abaxial surface; segments 5, in 1 plane, middle segment obtriangular, 3.1-7.2 mm wide at the base [ratio segment width at the base/middle segment length =

0.29-0.51], (1)3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.06-0.25]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; stipules 1.5-3.6 mm long, 0.5-1.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme or dichasial with monochasial branches; cymules 1-flowered, solitary [ratio cymule length/leaf length = 2.3-4.2]; peduncles 15-40(45) mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 5.7-7 mm long, 2.2-3.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.9 mm long [ratio mucro length/sepal length = 0.07-0.13], with erect-patent, eglandular hairs 0.3-0.6 mm long on the abaxial surface, ± glabrous adaxially. *Petals* 9.9-14.4 mm long, 3.8-6.1 mm wide, erect-patent, slightly emarginate (notch 0.3-0.5 mm deep), with claw 1.2-2.3 mm long, purple, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.6-5.2 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.6 mm long on the abaxial surface and margin; anthers 1.2-1.4 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.8-6.6 mm long, yellow. *Fruit* 12.4-18.8 mm long, erect, discharge of seed-ejection type; mericarps 2.7-3.6 mm long, 1.5-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.6 mm long; rostrum 8.2-12.4 mm long, with a narrowed apex 0.9-1.2 mm long, not twisted, with erect-patent, eglandular hairs 0.2-0.4 mm long; stigmatic remnants 1.8-2.1 mm

long, with 5 glabrous lobes. Seeds 1.9-2.3 mm long, 1.3-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 504, 505.

*Pollen.* Ornamentation not studied.  
*Chromosome number.* Unknown.

*Phenology.* Collected in flower from May to June.

*Distribution.* This species is endemic to La Libertad, in northern Peru (Fig. 506).

*Habitat.* Grassy slopes and shrublands; 3000-3800 m.

*Additional specimens examined. Peru.*

LA LIBERTAD: Sánchez Carrión prov., Huamachuco-Cajabamba, between Sausagocha and Cajabamba, 7°41'S, 78°1'W, 15 Feb. 1983, *Smith & Vásquez* 3370 (F, NY, USM); Huamachuco, pr. La Conga, 7°44'S, 77°59'W, 30 June 2009, *Aedo & Zapata* 16691 (MA); Sunchubamba, upper Chicama valley, 7°45'S, 78°38'W, 30 May 1957, *Ellenberg* 1650 (U); Sunchubamba, 7°45'S, 78°38'W, 8 June 1957, *Ellenberg* 1831 (U); provincia Huamachuco, cerca de Huamachuco, 7°48'S, 78°2'W, 17 Mar. 1948, *Ferreira* 3064 (USM).

*Discussion.* *Geranium renifolium* is well characterized by its 1-flowered cymules and its almost glabrous leaves, which are orbicular in outline, not deeply divided, with eglandular hairs restricted to the margins and nerves on the abaxial surface; rarely some sparse hairs are present between nerves. The leaves usually have the segments apically trilobulate; however, the segments are sometimes lanceolate and unlobed towards the apex of inflorescences. The hairs on stems, petioles, and pedicels are short, retrorse, appressed, and eglandular.

This species, described from southern Cajamarca, has also been found in a few localities in nearby La Libertad. The lectotype proposed by Knuth (1912: 159) is lost and no duplicates were found. Therefore, a neotype collected near the type locality and in agreement with the original description was designated.

**198. *Geranium stuebelii*** Hieron., Bot. Jahrb. Syst. 21: 316. 1895. TYPE LOCALITY: "Peruvia: crescit supra Tambo Mayo inter Pacasmayo et Moyobamba, mense Aprili-Junio florens (coll. peruv. n. 43 a)". TYPE: Peru. Cajamarca. Tambo Mayo inter Pacasmayo et Moyobamba, 7°05'S, 78°18'W, A. Stuebel 43a (no original material located). Peru. Cajamarca. pr. Cumbe Mayo, 7°11'S, 78°34'W, 15 June 2009, C. Aedo 16497 (neotype, designated by Aedo 2012: 291, MA-788284!).

*Perennial herbs*, 26-59 cm tall. *Root-stock* 6.2-8.3 mm in diameter,  $\pm$  vertical, not tuberculate,  $\pm$  turnip-shaped, without thickened roots. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-1.2 mm long and, sometimes, patent, glandular hairs 0.3-1.3 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas (1.7)1.8-3.1(3.4) cm long, 2-4.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.49)0.56-0.64(0.69)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed or patent, eglandular hairs and, usually, glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular to rhombic, 5.3-9.9 mm wide at the base [ratio segment width at the base/middle segment length = 0.36-0.49], 3-5(7)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.08-0.20]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1 mm long and, usually, patent, glandular hairs 0.2-0.8 mm long; stipules 2.9-4.9 mm long, 0.9-1.6 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = 1.6-3.8]; peduncles 22-41 mm long, with patent, eg-

Fig. 505. *Geranium renifolium* (Based on: Aedo & Zapata 16691, MA).

landular hairs 0.2-1 mm long and patent, glandular hairs 0.3-0.6 mm long; bracteoles 3-4 mm long, 0.6-0.7 mm wide, lanceolate, opposite; pedicels absent or 16-68(71) mm long, with patent, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* (4.9)5.7-6.5(8) mm long, 2-3.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.9 mm long [ratio mucro length/sepal

length = 0.04-0.14], with erect-patent, eglandular hairs 0.2-0.7 mm long and glandular hairs 0.3-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.4)10.4-11.7 mm long, 4.4-7 mm wide, erect-patent, slightly emarginate (notch 0.3-0.4 mm deep), without claw, white or pale pink, glabrous or sparsely ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.4-5.6 mm long,

lanceolate, yellow, with eglandular hairs 0.1-0.5 mm long on the abaxial surface and margin; anthers 1-1.2 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.3-6.4 mm long, yellow. *Fruit* 19.7-23.4 mm long, erect, discharge of seed-ejection type; mericarps 2.6-3.5 mm long, 1.6-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with erect-patent, eglandular hairs 0.1-0.9 mm long and patent, glandular hairs 0.3-1 mm long; rostrum 12.7-17 mm long, with a narrowed apex 1.4-2.8 mm long, not twisted, with patent, eglandular hairs 0.2-0.7 mm long and patent, glandular hairs 0.4-0.8 mm long; stigmatic remnants 1.7-2.8 mm long, with 5 glabrous lobes. *Seeds* 1.7-2.6 mm long, 1.3-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 507, 508.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to December.

*Distribution*. This species ranges through northern Peru (Fig. 509).

*Habitat*. Roadsides, rocky cliffs, open grassy areas, low shrublands, and forest remnants; 1800-3550 m.

*Additional specimens examined*. **Peru.**

**Discussion.** *Geranium stuebelli* is a robust species with very characteristic leaves, polygonal in outline and with acute lobes. The middle segment varies from obtriangular to rhombic and usually is 3-5-lobed at the apex; in some specimens a few leaves have the middle segment apically 7-lobed. A glandular indumentum is always present in the inflorescence and often also on stems and leaves. Glandular forms of *G. peruvianum* have leaves orbicular in outline and with an obtriangular middle segment with obtuse lobes, but without glandular hairs on the fruits. The petals of *G. peruvianum* and *G. stuebelli* have a short notch; those of *G. peruvianum* have distinctive claw, which is absent in *G. stuebelli*. The cymules of *G. stuebelli* lack pedicels and bracteoles in most of the inflorescence, although rarely 1-2 bracteoles can be found at pedicels in the lower portion of the inflorescence.

Because the holotype for *G. stuebelli* is no longer extant, a specimen matching the original description and collected in the area of the type locality in southern Cajamarca was designated as neotype.

**199. *Geranium peruvianum*** Hieron., Bot. Jahrb. Syst. 21: 316. 1895. TYPE LOCALITY: "Peruvia: crescit inter Pacasmayo et Moyobamba mense Aprili-Junio florens (coll. peruv. n. 51 d)". TYPE: Peru. **Discussion.** *Geranium peruvianum* shares with *G. renifolium* 1-flowered cymules and leaves orbicular in outline and not deeply divided, which are densely covered with patent hairs on both surfaces. The leaves usually have apically 3-lobulate segments; however, towards the apex of inflorescence they are sometimes lanceolate and not lobulate. The indumentum of *G. peruvianum* is usually eglandular, although some specimens have scattered glandular hairs at the sepal base and the pedicel apex. The specimen *Gutte & Müller* 9177 (USM) is an exception, and has glandular hairs spread on pedicels and stems, but aspects of the leaves and fruit place it with *G. peruvianum*. The cymules usually lack bracteoles, but the specimen *Sánchez* 10498 (MA) has a pair of cymules with bracteoles near the base of the inflorescence.

*Geranium peruvianum* was described from a collection obtained in southern Cajamarca. The lectotype proposed by Knuth (1912: 160) is lost, and no duplicate was found. Therefore, a neotype collected near the type locality and in agreement with the original description was designated.

**200. *Geranium comarapense*** R. Knuth, Meded. Rijks-Herb. 27: 69. 1915. TYPE LOCALITY: "Auf Bergwiesen bei Comarapa, ca. 2600 m (no. 2015b, bl. im April 1911.-- Typus!)". TYPE: Bolivia. Santa Cruz, Comarapa, 17°54'S, 64°28'W, Apr. 1911, *T. Herzog* 2015b (holotype, L-0018339!).

*Perennial herbs*, ca. 13 cm tall. *Root-stock* 5.1 mm in diameter, unknown

*roots.* *Stem* prostrate, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.4-0.5 mm long and patent, glandular hairs 0.4-0.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas 1.3-2.1 cm long, 1.5-2.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.61-0.64], orbicular in outline, base cordate, not coriaceous, with nerves not projected,

pilose, with patent, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 4.2-7.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.43-0.58], 3-5-lobed at the apex [ratio secondary sinus length/middle segment length = 0.19-0.21]; petioles up to 5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-0.5 mm long and patent, glandular hairs 0.3-0.5 mm long; stipules 1.8-2.7 mm long, 0.6-0.7 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = ca. 2.9]; peduncles 18-33 mm long, with patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.3-0.5 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 4.3-5 mm long, 1.8-2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-0.7 mm long [ratio mucro length/sepal length = 0.10-0.17], with erect-patent, eglandular hairs 0.3-0.7 mm long and patent, glandular hairs 0.3-0.4 mm long on the abaxial surface, almost glabrous adaxially. *Petals* unknown. *Stamens* 10, both whorls bearing anthers; filaments ca. 2.8 mm long, lanceolate, unknown color, with eglandular hairs 0.4 mm long on the abaxial surface and margin; anthers ca. 0.7 mm long, unknown color.

Nectaries 5, hemispheric, glabrous. *Gynoecium* ca. 4.4 mm long, unknown color. *Fruit* unknown. *Seeds* unknown. Cotyledons not studied. Fig. 513.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in April.

*Distribution*. This species is endemic to western Santa Cruz, Bolivia (Fig. 514).

*Habitat*. Unknown; ca. 2600 m.

*Discussion*. *Geranium comarapense* is known only from the holotype, collected in western Santa Cruz, Bolivia. The specimen lacks the rootstock, petals, and fruits. A very immature fruit shows some glandular hairs, which differentiates this species from *G. peruvianum*. The leaves are resemble those of *G. peruvianum*, and the stems and inflorescence are covered with glandular hairs. A distance of 1700 km separates the type locality of *G. comarapense* from the nearest population of *G. peruvianum*.

---

**The Rupicola Group**—This group is characterized by its erect or ascending habit, its opposite, palmatifid leaves and its 1-flowered cymules arranged in monochasial or, more rarely, in dichasial inflorescence. Except in *G. laxicaule*, the cymules of all or some nodes lack pedicels. The petals are usually of medium size and without claw, and the fruit rostrums usually have a narrowed apex.

*Perennial herbs*, 26-100(200) cm tall. *Rootstock* 6.5-9.8 mm in diameter, ± vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* ascending or climbing, leafy,

not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-1.8 mm long and, sometimes, patent, glandular hairs 0.2-1.3 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas (1.2)2.5-4.7(7.3) cm long, 2.1-7.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.63-0.87], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs and, sometimes, glandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic to obtriangular, 3.3-12.6 mm wide at the base [ratio segment width at the base/middle segment length = 0.16-0.41], 3-5(7)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.11-0.29]; petioles up to 31 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1.4 mm long and, usually, patent, glandular hairs 0.3-1.4 mm long; stipules 1.8-7 mm long, 0.9-3.9 mm wide, broadly lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, minutely hairy adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.3)0.6-1.3(1.8)]; peduncles 6.5-47 mm long, with patent, eglandular hairs 0.1-1 mm long and patent, glandular hairs 0.2-1 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 4.3-7 mm long, 1.7-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.1-0.7 mm long [ratio mucro length/sepal length = 0.02-0.12], with erect-patent, eglandular hairs 0.1-0.9 mm long and glandular hairs 0.4-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.4)6.5-7.9(9.4) mm long, 1.7-4.4 mm wide, erect-patent, rounded or slightly emarginate (notch 0.1-0.4 mm deep), without claw, purple, rarely white, glabrous or ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.2-3.5 mm long,

lanceolate, yellow, with eglandular hairs 0.1-0.3 mm long on the abaxial surface and margin; anthers 0.5-0.8 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.4-4.4 mm long, yellow. *Fruit* 17-21 mm long, erect, discharge of seed-ejection type; mericarps 2.3-3.8 mm long, 1.3-1.9 mm wide, without a strand of fibers, not compressed at the apex, smooth,

without basal beak, with a basal calus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.2-0.7 mm long; rostrum 12.9-15.8 mm long, with a narrowed apex 1.1-2.1 mm long, not twisted, with patent, eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 0.3-0.9 mm long; stigmatic remnants

**Discussion.** *Geranium chilloense* is characterized by its ascending or climbing habit, and its 1-flowered cymes that usually have short peduncles but lack pedicels and bracteoles. The peduncles are noticeably short towards the apex of inflorescence, where the flowers are sometimes almost sessile. A glandular indumentum is normally abundant on the inflorescence, although sometimes the glandular hairs are sparse and restricted to the apex of peduncles and sepals. In some specimens the glandular indumentum also extends to the base of the stems and petioles. Such variation can be found in the same specimen. The middle leaf segment is also variable, usually rhombic in outline but sometimes obtriangular. It usually has three to five lobes, although some specimens have seven lobes. Petal size is a useful feature for separating *G. chilloense* from *G. rupicola* and *G. laxicaule*, since *G. chilloense* has shorter petals (although with some overlap in a few specimens of *G. laxicaule*). The specimen *Aedo & al.* 13021 (MA) is an exception; a sin-

gle cymule near the inflorescence base has a short pedicel and a pair of bracteoles; the other cymules lack pedicels and bracteoles.

**202. *Geranium laxicaule* R. Knuth** in Engl., Pflanzenr. IV.129 (Heft 53): 209. 1912. TYPE LOCALITY: "Peru: An der Lima-Oroya-Bahn auf einem Bergstock südwestlich von Matucana im Hintergrunde des Thales von Huillacachi an einem kleinen Wasserfall, oberhalb 3000 m (Weberbauer a. 1901 n. 187 -- Typus in Herb. *Perennial herbs*, 25-54 cm tall. *Root-stock* 5.5-9.6 mm in diameter,  $\pm$  vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* ascending, leafy, rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-1.2 mm long and, usually, patent, glandular hairs 0.2-0.8 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminae 1.5-4.1 cm long, 1.9-4.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.63-0.83], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 2.5-7.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.16-0.34], 3-5-lobed at the apex [ratio secondary sinus length/middle segment length = 0.11-0.27]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with pat-

ent, eglandular hairs 0.2-1.4 mm long and, usually, patent, glandular hairs 0.3-0.4 mm long; stipules 3.1-6.6 mm long, 0.7-1.9 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, minutely hairy adaxial-

ly. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.6)1.1-2.1(2.8)]; peduncles 14-74 mm long, with patent, eglandular hairs 0.2-1.1 mm long and, usually, patent, glandular hairs 0.2-0.9 mm long; bracteoles

1.8-4.3 mm long, 0.6-1.2 mm wide, linear-lanceolate, opposite; pedicels 12-39 mm long, with patent, eglandular hairs 0.4-1.2 mm long and, usually, patent, glandular hairs 0.3-0.7 mm long. Flowers actinomorphic. *Sepals* 4.5-7.9 mm long, 1.9-3.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.7 mm long [ratio mucro length/sepal length = 0.06-0.14], with erect-patent, eglandular hairs 0.4-1 mm long and patent, glandular hairs 0.3-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.2)7.8-11.3(16.3) mm long, 2.8-6 mm wide, erect-patent, rounded or slightly emarginate (notch 0.4-0.6 mm deep), without claw, white or pale pink, glabrous or ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1.8-5 mm long, lanceolate, white, with eglandular hairs 0.1-0.3 mm long on the abaxial surface and margin; anthers 0.5-1.2 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.9-6.5 mm long, white. *Fruit* 15.4-25.4 mm long, erect, discharge of seed-ejection type; mericarps 2.9-3.8 mm long, 1.4-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.6 mm long; rostrum 10.5-18.2 mm long, with a narrowed apex 0.7-2.6 mm long, not twisted, with patent, eglandular hairs 0.2-0.5 mm long and, rarely, patent, glandular hairs 0.5-0.6 mm long; stigmatic remnants 0.9-1.8 mm long, with 5 glabrous lobes. *Seeds* 2.2-3 mm long, 1.3-1.9 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 518, 519.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to August.

*Distribution*. This species ranges through central Peru (Fig. 520).

*Habitat*. Open rocky slopes, cliffs, puna grassland and shrublands; 3000-4200 m.

**Discussion.** *Geranium laxicaule*, an endemic of central Peru, usually has glandular hairs at least on the inflorescence and 1-flowered cymules with a peduncle, bracteoles, and a pedicel. The glandular indumentum varies like that of *G. chilloense*; some specimens have a few glandular hairs (sparse and restricted to apex of pe-

duncles and sepals) and others lack them. The middle leaf segment is usually rhombic in outline, with five lobes, although there may be three lobes. Specimens with short petals can be distinguished from the sympatric *G. chilloense* by the bracteolate cymules. Because the holotype of *G. laxicaule* (Weberbauer 187) was destroyed, and no duplicate was found at USM and MOL, a neotype was designated (Aedo 2012: 303), which was collected also in Lima Department and matches the original description and the photograph of the holotype (F, G, NY).

Some specimens from Ecuador identified in herbaria as *G. laxicaule* have 2-flowered cymules and should be assigned to *G. killipii*.

**203. *Geranium ayacuchense* R. Knuth, Repert. Spec. Nov. Regni Veg. 18:291. 1922, [31 Dec. 1922].** TYPE LOCALITY: "Peru, Dept. Ayacucho, Prov. Huanta: Weg von Tambo über Osno zum Flusse Apurimac; in der Grassteppe, die von kleineren Strauchbeständen unterbrochen wird (Weberbauer, Fl. Peru a. 1910, no. 5563.-Typus in Herb. Berol.!).". Weberbauer 5563* (holotype, B destroyed; lectotype, designated by Aedo 2012: 306, F-0093172F!).

*Geranium scissum* R. Knuth, Repert. Spec. Nov. Regni Veg. 28:4. 1930, R. Knuth. TYPE LOCALITY: "Peru: Paucartambo, Hacienda Churu (Herrera n. 1916 -- Typus in herb. Berol.!).". TYPE: Peru. Cuzco, Paucartambo, Hacienda Churú, 13°18'S, 71°35'W, *F. Herrera 1916* (holotype, B destroyed, no original material located).

**Perennial herbs**, 15-41 cm tall. **Root-stock** 4-7.9 mm in diameter, ± vertical, not tuberculate, turnip-shaped, without thickened roots. **Stem** ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse to patent, eglandular hairs 0.2-1.2 mm long. **Basal leaves** in a ± persistent rosette, cauline

leaves opposite; leaf laminas (1.1)1.8-2.6(3.1) cm long, 1.3-4.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.68)0.72-0.86], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 1.3-6 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.38], 3-5(7)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.18-0.34]; petioles up to 11 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, appressed, eglandular hairs 0.2-1.4 mm long; stipules 2-5.7 mm long, 0.6-1.7 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (1.3)1.7-3.8]; peduncles 7.9-73.5 mm long, with retrorse to patent, eglandular hairs 0.2-1 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* (4.7)6.2-7.8(8.9) mm long, 2-4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.3)0.6-1(1.1) mm long [ratio mucro length/sepal length = 0.07-0.14(0.19)], with erect-patent, eglandular hairs 0.3-1.5 mm long on the abaxial surface,  $\pm$  hairy adaxially. *Petals* (9.8)11.5-14.1(15.4) mm long, 4.7-9 mm wide, erect-patent, slightly emarginate (notch 0.3-1 mm deep), with claw 0.8-2.6 mm long, white, hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.7-6.6 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.9 mm long on the abaxial surface and margin; anthers 0.7-1.3 mm long, yellow. Nectaries 5, hemispheric, usually hairy. *Gynoecium* 3.6-7.2 mm long, unknown color. *Fruit* 15.4-22.8(25) mm long, erect, discharge of seed-ejection type; mericarps 3-3.6 mm long, 1.2-2.3 mm wide, without a strand of

fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-0.7 mm long; rostrum 9.2-18.5 mm long, with a narrowed apex (0)0.6-1.2(1.3) mm long, not twisted, with patent, eglandular hairs 0.1-0.6 mm long; stigmatic remnants 2.1-3.3

mm long, with 5 glabrous lobes. *Seeds* 2-2.7 mm long, 1-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 521.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

Fig. 521. *Geranium ayacuchense*. a. Habit. b, c. Leaves, adaxial side. d. Stipules. e. Flower, sepals and petals removed. f. Sepal. g. Petal. h. Staminal filament. i. Fruit. j. Mericarp. k. Seed. **Discussion.** *Geranium ayacuchense* is difficult to separate from *G. leucanthum* and from the eglandular forms of *G. rupicola*, because they have many quantitative characters that almost always overlap to some extent. The three species share cymules without pedicels and bracteoles for most part of the inflorescence, although sometimes 1-2 bracteoles can be found at the basal cymules. Specimens with some cymules that have peduncles, pedicels and bracteoles are exceptional in *G. ayacuchense* but more common in *G. leucanthum* and *G. rupicola*. The leaves of *G. ayacuchense* are shorter than in *G. leucanthum* and *G. rupicola*, and the middle segment is obtriangular, a useful distinguishing character that separates it from *G. leucanthum*. Additionally, in *G. ayacuchense* the lobes of the middle segment are fewer than in the other two species, but with some overlap. The inflorescence of *G. ayacuchense* is monochasial; it is dichasial in *G. leucanthum* and dichasial with monochasial branches in *G. rupicola*. The cymules are usually much longer than adjacent leaves in *G. ayacuchense*, unlike in *G. leucanthum*. Sepals of *G. ayacuchense* have a shorter mucro, and the petals are shorter than in *G. rupicola*; the petals are of similar length to those of *G. leucanthum* but with a distinct claw. Staminal filaments, anthers, fruits,

and mericarps are shorter in *G. leucanthum* than in *G. ayacuchense* but with some overlap. The fruit rostrum has a narrowed apex in all three species, although it is longer in *G. leucanthum* and *G. rupicola* than in *G. ayacuchense*. The stigmatic remnants of *G. ayacuchense* are similar in length to those of *G. rupicola* and longer than those of *G. leucanthum*. Seeds are glabrous in both *G. ayacuchense* and *G. leucanthum*. The southernmost populations recorded for *G. ayacuchense* in southern Peru are more than 500 km distant from the nearest places where *G. rupicola* occurs, and more than 1000 km distant from the range of *G. leucanthum*. A collection from Cuzco (*Solomon* 3038) has the leaves deeply divided but matches *G. ayacuchense* otherwise. No original material of *G. scissum* (*Herrera* 1916) was located, but a collection from the type locality, *Herrera* 1017 (F!, US!), aided in the interpretation of this name. These specimens have large petals, 1-flowered cymules without pedicels, and an eglandular indumentum, like those found in *G. ayacuchense*.

*Perennial herbs*, 14-73 cm tall. *Rootstock* 3.5-10(21.5) mm in diameter,  $\pm$  vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse to patent, eglandular hairs 0.2-1.7 mm long and, sometimes, patent, glandular hairs 0.4-0.8 mm long. *Basal leaves* in a  $\pm$  persistent rosette,

cauline leaves opposite; leaf laminae (1.5)3-4.2(8) cm long, 2-8.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.86(0.91)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 2.5-13.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.41], (3)5-9(14)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.16-0.41]; petioles up to 31 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse to patent, eglandular hairs 0.2-1.4 mm long and, sometimes, patent, glandular hairs 0.3-0.6 mm long; stipules 1.9-11 mm long, 0.5-3 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme with monochasial branches; cymules 1-flowered, solitary [ratio cymule length/leaf length = 1-3]; peduncles 20-170 mm long, with retrorse to patent, eglandular hairs 0.2-1.3 mm long and, sometimes, patent, glandular hairs 0.2-1 mm long; bracteoles 3.2-9.1 mm long, 0.5-1.4 mm wide, linear-lanceolate, opposite; pedicels absent or 5.7-90 mm long, with retrorse to patent, eglandular hairs 0.2-1.5 mm long and, sometimes, patent, glandular hairs 0.2-1 mm long. Flowers actinomorphic. *Sepals* (5.6)7.7-9.9(12.3) mm long, 2.4-5.2 mm wide, lanceolate, smooth, not accrescent, nerves 3(5), mucro (0.6)1.1-2.8 mm long [ratio mucro length/sepal length = 0.08-0.26], with erect-patent, eglandular hairs 0.2-1.4 mm long and, sometimes, glandular hairs 0.2-1.1 mm long on the abaxial surface,  $\pm$  glabrous adaxially. *Petals* (10.7)13.2-16.9(19.2) mm long, 4.2-14.4 mm wide, erect-patent, rounded or slightly emarginate (notch 0.3-0.9 mm deep), without claw, white, pink or dark purple, hairy on the base of the adaxial surface, ciliate on

the basal margin, with hairs 0.2-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4-7.8 mm long, lanceolate, yellow, with eglandular hairs 0.2-0.8 mm long on the abaxial surface and margin; anthers 1.1-2.3 mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 4.3-9.2 mm long, red. *Fruit* (14.2)21-34.6 mm long, erect, discharge of seed-ejection type; mericarps 2.7-5.5 mm long, 1.7-2.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-1.2 mm long and, rarely, patent, glandular hairs 0.4-0.8 mm long; rostrum 8.5-24.8 mm long, with a narrowed apex (0.8)1.1-1.9(2.7) mm long, not twisted, with patent, eglandular hairs 0.2-1.1 mm long and, rarely, patent, glandular hairs 0.6-1 mm long; stigmatic remnants 1.8-4.7 mm long, with 5 glabrous lobes. *Seeds* 1.9-3.1 mm long, 1.2-2.3 mm wide, finely reticulate, slightly mottled, brown, hairy. Cotyledons with entire margin. Fig. 523.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 429).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from October to March.

*Distribution*. This species ranges from central Bolivia to northwestern Argentina (Fig. 524).

*Habitat*. Wet crevices in shade places, grassy slopes, stony hillsides, slopes with ball cacti and shrubs and at edge of forests; 1750-4000 m.

*Additional specimens examined*. **Argentina**. CATAMARCA: Andalgalá, Río Vallecito, 27°17'S, 66°4'W, 3 Mar. 1942, Rohmeder s.n. **Discussion.** *Geranium rupicola* is a species well characterized by its large petals, 1-flowered cymules, and hairy seeds, the last a unique condition in the entire genus. Petal color varies from white to deep purple. Some specimens from central and southern Bolivia have remarkably dark purple petals even in old herbarium material. The cymules at the apex of the inflorescence are always ebracteolate and lack a pedicel. Towards the base of inflorescence some cymules with a peduncle, bracteoles and pedicels can usually be found, but in some poorly prepared herbarium specimens these cymules are difficult to discern. Density of indumentum is variable. Young specimens usually have a dense indumentum, which mostly disappears in mature plants. Some specimens are eglandular, whereas others are densely covered with glandular hairs from the stem base to the sepals. Be-

tween these extremes are many transitional forms with a variable glandular indumentum. Variations in petal color, cymule structure, leaf shape, and indumentum are not correlated, and many different combinations can be found.

Knuth (1912: 149) characterized *G. rupicola* by its patent hairs and 1-flowered cymules and considered it very similar to *G. superbum*. Knuth (1912: 140) also stated that *G. superbum* may have 1-flowered cymules. These notes suggest that *G. superbum* was described from heterogeneous material. Two syntypes are listed in the protologue: "Bolivia: auf Felsen der höchsten Stellen der Provinz Cinti (Weddel).—Peru: an der Lima-Oroya-Bahn zwischen Puente di Arichi und Chicla auf einer kleinen Wiese am Ufer eines Baches bei 3450-3700 m (Weberbauer n. 259!)" The *Weberbauer 259* specimen is lost, and a duplicate at P of the Weddell collection was chosen as lectotype. Thus, *G. superbum* is a superfluous name for *G. rupicola*. *Geranium sepalo-roseum* was described from a collection obtained at "Capi", Bolivia; I found a small locality with this name in western Oruro (18°47'S, 68°11'W). Yet, it is doubtful that the type was collected in this area, since it is a region of dry puna, a habitat where this species has never been found. Most likely, the type collection was mislabeled. Knuth (1933) designated as holotype of *G. cuchillense* a sheet at B (Bolivia: Chuquisaca, Sucre, Tomina, Alto de Cuchilla, 1927, *Troll 881*). This specimen was destroyed, and no duplicate has been found. Yet, Knuth's original description (1933) fits well with *G. rupicola*, and the type locality falls within the range of *G. rupicola*. Therefore, *G. cuchillense* is here considered a synonym of *G. rupicola*.

**205. *Geranium soratae*** R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 212. 1912. TYPE LOCALITY: "Bolivia: Sorata, 3300 m. (Rusby, Fl. South-America a.

*Perennial herbs*, 18-59 cm tall. *Root-stock* 4.6-19.9 mm in diameter,  $\pm$  vertical, not tuberculate, turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae 1.9-3.3 cm long, 2-4.3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.77-0.85], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 2.2-5.7 mm wide at the base [ratio segment width at the base/middle segment length = 0.13-0.21], 6-9-lobed at the apex [ratio secondary sinus length/middle segment length = 0.23-0.40]; petioles up to 7.3 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules 2.7-9.5 mm long, 1.2-2.5 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, solitary [ratio cymule length/leaf length = (0.7)1-1.5(2.3)]; peduncles 15-25(70) mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long; bracteoles absent. Flowers actinomorphic. *Sepals* 4.2-5.6 mm long, 1.6-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.9 mm long [ratio mucro length/sepal length = 0.09-0.16], with erect-patent, eglandular hairs

0.1-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* 7.1-9.9(10.2) mm long, 2.4-4 mm wide, erect-patent, rounded, without claw, white, glabrous or hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.5-4.6 mm long,

lanceolate, yellow, with eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers 0.7-1.2 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4-4.6 mm long, unknown color. *Fruit* 13.1-14.8 mm long, erect, discharge of seed-ejection type; mericarps 2.3-2.8 mm long, 1-1.3 mm wide, without

a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.2-0.4 mm long; rostrum 8.8-11.2 mm long, without a narrowed apex, sometimes with a narrowed apex ca. 0.7 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 0.8-1.3 mm long, with 5 glabrous lobes. *Seeds* 1.7-1.8 mm long, 1.1-1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 525.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from December to February.

*Distribution*. This species is endemic to western Bolivia (Fig. 526).

*Habitat*. Rocky and shrublands, and edge of *Polylepis* Ruiz & Pav. forests; 2650-3650 m.

*Additional specimens examined*. **Bolivia.**

LA PAZ: Larejaca, Sorata, 55 kms hacia Consata, sobre camino de altura, 15°26'S, 68°36'W, 16 Dec. 1981, Beck 4981 (MA, U); Larejaca, Sorata, Cerro del Inimapi, 15°43'S, 68°38'W, Feb. 1859, Mandon 778 (BM, G, NY, P, W); Sorata, 15°46'S, 68°38'W, Feb., Rusby 760 (MO); Sorata, 15°46'S, 68°38'W, Feb., Rusby 760 (W); Sorata, 15°46'S, 68°38'W, 1886, Rusby 761 (NY).

*Discussion*. *Geranium soratae*, an endemic of northern Bolivia known from only few localities, is well char-

Fig. 525. *Geranium soratae*. a. Habit. b. Leaf, adaxial side. c. Stipules. d. Flower, sepals and petals removed. e. Sepal. f. Petal. g. Staminal filament. h. Fruit. i. Mericarp. j. Seed. (Based on: a, c-g, Mandon 778, P; b, Rusby 763, F; h-j, Rusby 760, MO).

Fig. 526. Distribution of *Geranium soratae*.

acterized by its 1-flowered cymules without a pedicel and bracteoles, and by its short, narrow petals. Its indumentum is eglandular and, in young specimens, is usually dense and whitish. The leaves are deeply divided and have a rhombic middle segment, and the fruit rostrum usually ends abruptly (without a narrowed apex). The type collection of *G. soratae*, Rusby 763, is a mixed gathering; the sheet at MO is *G. diffusum*. Among the duplicates of Rusby 760 are two sheets, at MO and W, that are *G. soratae*; the other specimens, at BM, F, GH, K, P, and US, constitute the type collection of *G. bolivianum*, a synonym of *G. fallax*.

**Discussion.** *Geranium leucanthum* is difficult to separate from the eglandular forms of *G. rupicola*. Both share long petals and 1-flowered cymules that are ebracteolate towards the apex of the inflorescence, although basal ones sometimes have pedicels and bracteoles. The range of *G. leucanthum* partially overlaps that of *G. rupicola*. The species differ in that the seeds of *G. leucanthum* are glabrous, its indumentum is always eglandular, and its petals are white or pale pink, but never dark purple, as in some specimens of *G. rupicola*. In general, the sepals, petals, and anthers are shorter in *G. leucanthum* than in *G. rupicola*. Barboza (1996) distinguished *G. leucanthum* as a species with palmatisect, discolorous leaves, a long calyx, and sometimes glandular vestiture from *G. delphinifolium*, characterized as an eglandular and more robust species, with palmatipartite, concolorous leaves and a short calyx, and first collected in the vicinity of Tafí. Study of the many collections available from this region show *G. delphinifolium* to be a robust variant of *G. leucanthum*, and no character or suite of characters consistently supports

recognition of two species. In addition, Barboza's (1996) account of *G. leucanthum* suggests that specimens here identified as *G. rupicola* were included in her assessment.

**The Multiceps Group**—This group is characterized by its usually erect habit, its opposite leaves and its 2-flowered cymules arranged in a dichasial inflorescence. The first five species constitute a subgroup with thicker leaves (sometimes leathery), stem leaves cuneate to truncate at the base, and petals usually with a short claw.

*Perennial herbs*, 10-20(60) cm tall. *Rootstock* 3-8.3 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with  $\pm$  thickened roots. *Stem* erect or ascending, leafy (rarely scapiform), not rooting at nodes, stolons absent, without vegetative stems, with usually retrorse, appressed, eglandular hairs 0.1-1.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite (cuneate to truncate, with usually 3(5) entire segments); leaf laminae (0.7)1.7-2.2(6.4) cm long, (0.9)2.4-3.1(8.3) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.58-0.84], polygonal in outline, base cuneate to subtruncate, rarely cordate, not coriaceous, nerves  $\pm$  projected on the abaxial surface, sunken adaxially, usually with short, patent, eglandular hairs restricted to margin, rarely scattered hairs on both surfaces; segments (3)5, curved, middle segment obtriangular, 2-5(16) mm wide at the base [ratio segment width at the base/middle segment length = 0.21-0.36], 3(5)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.06-0.30]; petioles up to 5(30) cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed (sometimes patent), eglandular hairs 0.1-0.8 mm long; stipules 1.9-8 mm long, 0.8-2.6 mm wide, subulate, free, papery, brownish red, subglabrous on abaxial surface, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.2-9.8]; peduncles 10-55 mm long, with usually retrorse,  $\pm$  appressed, eglandular hairs 0.1-1.1 mm long; bracteoles 1.6-4 mm long, 0.5-2 mm wide, lanceolate, whorled; pedicels 8-30 mm long, with usually retrorse,  $\pm$  appressed, eglandular hairs 0.1-0.9 mm long. Flowers actinomorphic. *Sepals* 5.1-8 mm long, 1.7-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.3-0.7 mm long [ratio mucro length/sepal length = 0.05-0.14], with antrorse, appressed, eglandular hairs 0.2-0.9 mm long at

least on the nerves of abaxial surface and margin, glabrous adaxially. *Petals* 8.6-11(12) mm long, 3.4-5(7.5) mm wide, erect-patent, rounded or slightly emarginate (notch ca. 0.5 mm deep), with claw 1-3.8 mm long, purple, sometimes white with purplish veins, glabrous, rarely with scattered hairs on base of abaxial surface, with hairs 0.1-0.3 mm long. *Stamens* 10,

both whorls bearing anthers; filaments 3-5 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.2-0.4 mm long; anthers 0.8-1.2 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.8-5.5 mm long, red. *Fruit* 13-17 mm long, erect, discharge of seed-ejection type; mericarps 2-3.5

mm long, 1.1-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with abundant antrorse, appressed, eglandular hairs 0.1-0.6 mm long; rostrum 8.3-12 mm long, without a narrowed apex, not twisted, with abundant antrorse, appressed, eglandular hairs 0.1-0.7 mm long; stigmatic remnants 1.5-3 mm long, with 5 subglabrous lobes. *Seeds* 1.5-2 mm long, 0.9-1.2 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 530, 531.

*Pollen*. *Geranium*-type (Aedo & al. 2003: 99; Bortenschlager 1967: 427).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to October.

*Distribution*. This species ranges through western Venezuela (Fig. 532).

*Habitat*. Banks of pool and streams, bogs, grassy or rocky places, in open slopes dominated by *Espeletia* Mutis ex Bonpl.; 3000-4450 m.

*Representative specimens examined*.

Cava, 9°2'N, 70°30'W, 30 July 2010, *Grande & Aedo* 2483 (MA).

*Discussion.* *Geranium multiceps* is easy to identify by its membranaceous, cuneate to subtruncate, funnel-shaped leaves, and the erect mature. *Geranium lainzii* is quite similar to *G. multiceps* but with coriaceous, subtruncate, flat leaves, usually with three segments, and reflexed mature fruits. *Geranium multiceps* is endemic to Venezuela; and records from Colombia in the literature should be corrected to *G. lainzii*. The unusual leaf of *G. multiceps* is best seen in living plants. The lamina is vertical and the lateral segments are recurved such that they almost touch one another, giving a funnel-like aspect to the leaf. In herbarium specimens the lateral leaf segments are usually folded over the middle one, and the cuneate shape of the leaf base is accentuated. In *G. multiceps* the leaves usually have very short eglandular hairs on the nerves, spreading patent hairs on the margins, and eglandular hairs restricted to the nerves of the abaxial surface. An unusual collection from Trujillo (*Grande & Aedo* 2532, MA, VEN) has leaves with only three segments and a more rigid posture, quite similar to leaves of *G. lainzii*; however, the fruits are erect (not reflexed, as in *G. lainzii*), and the leaves have curved segments as described above for *G. multiceps*. The variant plants grow in swampy areas, whereas populations with the usual morphology occur on the nearest dry slopes. At contact points intermediates are found, which indicate that the variants do not merit taxonomic recognition.

Sandwith (1942: 220) delimited *G. tracyi* on the basis of habit and a spreading indumentum on stems and inflorescence. Still, Sandwith suggested that *G. multiceps* is a variable species in these characters, and that field investigations would determine the status of *G. tracyi*. Study of the many herbarium specimens of *G. multiceps* showed that the type collection of *G. tracyi* falls within the variation found in *G. multiceps*.

**208. *Geranium cavanillesii* Aedo, sp. nov.** TYPE: Colombia? Columbia, paramo de Diacono, *Engels s.n.* (LE!, holotype).

*Perennial herbs*, 5-9 cm tall. *Root-stock* ca. 22 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf lamina 1.2-1.5 cm long, 0.8-1 cm wide, not peltate, digitate (lateral segments upward) [ratio main-sinus length/middle segment length = 0.46-0.63], obtriangular in outline, base cuneate, not coriaceous, with nerves not projected, usually with short, patent, eglandular hairs restricted to margin, rarely scattered hairs on both surfaces; segments 3, in 1 plane, middle segment obtriangular, 1.6-1.7 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.14], 3-lobed at the apex [ratio secondary sinus length/middle segment length = 0.07-0.11]; petioles up to 2.4 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.3 mm long; stipules 11-13 mm long, 1.2-1.8 mm wide, subulate, free, papery, brownish red, subglabrous on abaxial surface, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.5-4.3]; peduncles 27-32 mm long, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; bracteoles 1.1-3.1 mm long, 0.6-0.7 mm wide, lanceolate, whorled; pedicels 14-21 mm long, with retrorse, appressed, hairs eglandular 0.1-0.2 mm long. *Sepals* 6.4-6.7 mm long, 1.7-2.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-0.6 mm long [ratio mucro length/sepal length = 0.08-0.10], with antrorse, appressed, eglandular hairs 0.2-0.3 mm long at least on the

nerves of abaxial surface and margin, glabrous adaxially. *Petals* unknown. *Stamens* 10, both whorls bearing anthers; filaments ca. 4 mm long, lanceolate, unknown color, with eglandular hairs ca. 0.2 mm long on the abaxial surface and margin; anthers unknown. Nectaries 5, hemispheric, glabrous. *Fruit* 14-15 mm long, erect, discharge of seed-ejection type; mericarps ca. 3 mm long, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown; rostrum ca. 9 mm long, with a narrowed apex ca. 1 mm long, not twisted, with abundant erect-patent, eglandular hairs 0.1-0.6 mm long; stigmatic remnants ca. 1.9 mm long, with 5 glabrous lobes. *Seeds* unknown. Cotyledons not studied. Fig. 533.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Unknown.

*Distribution*. This species ranges probably from Colombia or Venezuela.

*Habitat*. Unknown.

*Discussion*. *Geranium cavanillesii* is known only from the holotype. The sheet consists in three fragments that lack a well-developed rootstock, roots, petals, anthers and seeds. Thus, the description is incomplete and should be improved when more collections became available. *Geranium cavanillesii* seems close to *G. multiceps* in its general aspect, inflorescence structure, stipules, indumentum, and fruit position. However, it is easy to differentiate from *G. multiceps* by the shape of its leaves. The leaf lamina of *G. multiceps* is palmatifid, with five segments, polygonal in outline whereas those of *G. cavanillesii* is more narrow, digitate, with three segments and obtriangular in outline. In fact the leaf of *G. cavanillesii* resembles those of *G. cuneatum*, a species endemic to Hawaii. This is probably the reason for which it was originally identified as "*Geranium cuneatum*" in the field label. *Geranium cavanillesii* differs fur-

ther in having a fruit rostrum with a narrowed apex not found neither *G. multiceps* nor close species.

According to the label of the type this plant was collected in "Columbia, paramo de Diacono". It has not been possible to locate this place either in Colombia or in Venezuela. The true identity of the collector also could not be fully resolved. The label reads

*Engels*, who could be Theodor Franz Engel (1834-1920), a German with gardening studies who was in Venezuela in 1855-57 (Rodríguez 1999). Some other collections attributed to *Engels* have been found, such as that of *Centronia pulchra* Cogn. (BR-0000005628964), whose label reads: "Venezuela ad Merida: Engels in h. hort. Petr.", but this has not aided in

Fig. 533. *Geranium cavanillesii*. a. Habit. b. Leaf. c. Stipules. d, e. Bracteoles. f. Sepals. g. Fruit. (Based on: Engels s.n., LE).

accurately determining the locality of *G. cavanillesii*, nor has it clarified the identity of the collector.

Both the scarcity of the material and the difficulties in locating its origin have resulted in an obstacle to describing this species which I had in my hands for many years. Finally, with a broader knowledge of the genus the importance of the above mentioned features become clear and support the decision to propose this new species.

**209. *Geranium lainzii*** Aedo, Anales Jard. Bot. Madrid 57: 162. 1999. TYPE LOCALITY: "Colombia. Cundinamarca, Páramo de Guasca en el cerrito del Santuario, Cuatrecasas 2273 (MA-252510!)" TYPE: Colombia. Cundinamarca, Páramo de Guasca en el cerrito del Santuario, 4°50'N, 73°50'W, 25 Apr. 1932, J. Cuatrecasas 2273 (holotype, MA-252510!).

*Perennial herbs*, 7-50 cm tall. *Root-stock* 3-9.5 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with  $\pm$  thickened roots. *Stem* ascending, leafy (rarely scapiform), not rooting at nodes, stolons absent, without vegetative stems, glabrous or with patent to retrorse, eglandular hairs 0.1-0.3(0.6) mm long (on a longitudinal line). *Basal leaves* in a persistent rosette, cauline leaves opposite (cuneate to truncate, with usually (1)3 entire segments); leaf laminae 0.9-3.2 cm long, 1-4.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.50-0.80], polygonal in outline, base subtruncate, coriaceous, with nerves projected on the abaxial surface, sunken adaxially, with some eglandular hairs at the end of each segment and near the margin (sometimes with patent cilia), abaxially glabrous; segments 3(5), in 1 plane, middle segment obtriangular, 2.5-7(10.7) mm wide at the base [ratio segment width at the base/middle segment length = 0.26-0.46], 3-lobed at the apex [ratio secondary

sinus length/middle segment length = 0.08-0.23]; petioles up to 10(20) cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.1-0.8 mm long; stipules 3-6(10) mm long, 1.1-2(4) mm wide, subulate, free, papery, brownish red, with eglandular hairs on the margin, subglabrous on abaxial surface and glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.2-5.6]; peduncles 11-70(150) mm long, with retrorse to patent, eglandular hairs 0.2-0.9 mm long; bracteoles 2-7 mm long, 0.8-2 mm wide, subulate, whorled; pedicels 16-47 mm long, with retrorse to patent, eglandular hairs 0.1-0.5 mm long. Flowers actinomorphic. *Sepals* 6.1-9 mm long, 1.9-3.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-1.3 mm long [ratio mucro length/sepal length = 0.08-0.18], with antrorse,  $\pm$  appressed, eglandular hairs 0.15-0.9 mm long, at least on the nerves and margin on the abaxial surface, glabrous adaxially. *Petals* (10.5)12-14.5 mm long, 4-8 mm wide, erect-patent, rounded or slightly emarginate (notch 0.5-0.7 mm deep), with claw 1.3-2.8 mm long, purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 3.6-6 mm long, lanceolate, yellow, glabrous on both surfaces, ciliate on the proximal half, with eglandular hairs 0.1-0.2 mm long; anthers 1-1.4 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4-5.5 mm long, yellow. *Fruit* 14-21.4 mm long, reflexed, discharge of seed-ejection type; mericarps 2.7-3.5 mm long, 1.2-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with abundant erect-patent, eglandular hairs 0.1-0.5 mm long; rostrum 7.8-12.8 mm long, without a narrowed apex, not twisted, with abundant erect-patent, eglandular hairs 0.1-0.5 mm long; stigmatic remnants 2-3 mm long, with 5 subglabrous lobes. *Seeds* 1.8-2.3 mm long,

0.9-1.6 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 534.

*Pollen*. *Geranium*-type (Aedo & al. 2003: 98).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges through central Colombia (Fig. 535).

*Habitat*. Margins of pools, bogs, and other grassy, damp areas, among patches of *Espeletia* Mutis ex Bonpl. and *Puya* Molina; 2400-4000 m.

*Representative specimens examined*.

**Discussion.** *Geranium lainzii* is easily to separate from *G. multiceps* by its coriaceous, subtruncate, flat leaves with usually three segments, and by its reflexed mature fruits; in *G. multiceps* the membranaceous, cuneate to subtruncate, funnel-shaped leaves have five segments, and the mature fruits are erect. *Geranium lainzii* is restricted to Colombia. Some Colombian specimens were erroneously identified as *G. multiceps*, perhaps in agreement with Knuth's drawing

Castillo '99

Fig. 534. *Geranium lainzii*. a. Habit. b. Detail of leaf, adaxial side. c. Peduncle. d. Sepal. e. Petal. f. Staminal filament. g. Fruit. h. Mericarp. i. Seed. (Based on: a, *Hatheway & Idobro* 1083, COL; b-g, *Cuatrecasas* 5550, US; h, i, *Langenheim & al.* 3683, US).

Fig. 535. Distribution of *Geranium lainzii*.

(1912: 105, fig. 18). Knuth's circumscription *G. multiceps* was based in part on collections of *G. lainzii*, but only the Venezuelan specimens he listed are *G. multiceps*. This confusion was already noted by Sandwith (1942: 220), who stated: "... the distinctive plant which is common around Bogotá in Colombia and has been identified with *G. multiceps* by all authors since Triana is certainly not the "typical" form of that species ..." *Geranium lainzii* superficially resembles *G. santanderiense*, which differs by its cordate leaves with five segments, antrorse appressed cilia on the margins, and eglandular hairs on the abaxial surface (vs. subtruncate leaves with three segments, glabrous abaxially and with scattered patent cilia). Some small specimens of *G. lainzii* have scapiform cymules; such reduced individuals always have 2-flowered cymules, which separate it from species with 1-flowered cymules allied with *G. sibbaldioides*.

**210. *Geranium santanderiense*** R. Knuth, Repert. Spec. Nov. Regni Veg. 18: 291. 1922, [31 Dec. 1922]. TYPE LOCALITY: "Columbien, Dept. Santander: Serra Pelada, an Bergabhängen zwischen Moosen, 3600 m (Kalbreyer a. 1878, no. 715.-Typus in Herb. Berol.!).". TYPE: Colombia. Ocaña to Pamplona, 7°50'N, 73°10'W, 30 Aug. 1878, W. Kalbreyer 715 (holotype, B destroyed; lectotype, designated by Aedo & al. 2003: 112, K-000531426!).

*Perennial herbs*, (10)15-60 cm tall. *Rootstock* 4.4-12 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.3-0.7 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite (cuneate to truncate, with usually 1(3) entire segments); leaf laminae 0.9-3.9(5.5) cm long, 1.5-

4.9(6) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.47-0.57], orbicular in outline, base cordate, coriaceous, with nerves projected on the abaxial surface, sunken adaxially, usually glabrous on the adaxial surface (sometimes hairy, mainly on nerve channels), densely ciliated (with antrorse, appressed, eglandular hairs) and with eglandular hairs on the nerves of abaxial surface; segments 5, in 1 plane, middle segment obtriangular, 4-9 mm wide at the base [ratio segment width at the base/middle segment length = 0.25-0.49], 3-lobed in distal half [ratio secondary sinus length/middle segment length = 0.07-0.20]; petioles up to 15(40) cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long; stipules 2-4.9 mm long, 0.8-1.7 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.9-6.5]; peduncles 22-70(92) mm long, with retrorse, appressed, eglandular hairs 0.3-0.7 mm long; bracteoles 2-5.7 mm long, 0.6-1.5 mm wide, lanceolate, whorled; pedicels 14-50 mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. Flowers actinomorphic. *Sepals* 5-6(9) mm long, 1.8-2.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.8 mm long [ratio mucro length/sepal length = 0.05-0.12], with antrorse, appressed, eglandular hairs 0.15-1 mm long at least on nerves and margin on the abaxial surface, glabrous adaxially. *Petals* (9.3)12-16 mm long, 5.3-9 mm wide, erect-patent, rounded or slightly emarginate (notch ca. 0.5 mm deep), with claw 1-2 mm long, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.7-5 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the

proximal half, with eglandular hairs 0.2-0.6 mm long; anthers 0.8-1.2 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4-6.4 mm long, purple. *Fruit* 14.6-21 mm long, reflexed, discharge of seed-ejection type; mericarps 2.1-3.5 mm long, 1.2-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with abundant erect-patent, eglandular hairs 0.3-0.5 mm long; rostrum 8.7-17 mm long, without a narrowed apex, not twisted, with abundant erect-patent, eglandular hairs 0.1-0.5 mm long; stigmatic remnants 1.9-3 mm long, with 5 subglabrous lobes. *Seeds* 1.5-2.1 mm long, 1.1-1.2 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 536.

*Pollen*. *Geranium*-type (Aedo & al. 2003: 98).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from western Venezuela to central and southwestern Colombia (Fig. 537).

*Habitat*. Roadside banks, grassy areas, open rocky hillsides, brushy slopes, bogs, among patches of *Espeletia* Mutis ex Bonpl. and *Polylepis* Ruiz & Pav.; 2600-4000 m.

*Representative specimens examined*.

**Discussion.** *Geranium santanderiense* is readily distinguished from other species allied with *G. multiceps* by its leaves, which bear antrorse, appressed cilia on the margin, giving a scarious appearance. *Geranium santanderiense* and *G. lainzii* share an eglandular indumentum on all parts of the plant and fruits that are reflexed at maturity. Both have small cauline leaves, sometimes reduced to a single lanceolate segment and are sympatric, although *G. santanderiense* has a wider range. See the discussion of *G. lainzii* for an account of the differences between the two species. Some specimens from the Sierra Nevada de Cocuy, Bocayá, Colombia (*Cuatrecasas* 1441a, *Grubb & al.* 195, *Cleef* 10008), and the Páramo de la Pata del Judío, Apure, Venezuela (*Steyermark & Dunsterville* 101141), show an unusual leaf indumentum: eglandular, appressed hairs 1.3 mm long on the adaxial surface, and eglandular hairs only on the nerves of the abaxial surface. Otherwise, they are similar to the other specimens of *G. santanderiense*.

**211. *Geranium jaramilloi*** Aedo, Feddes Repert. 120: 317, 318 fig. 1. 2009. TYPE LOCALITY: "Colombia. Santander, Onzaga, vereda de Chaguacá, alto de la laguna de Los Bobos, filo divisorio con Boyacá, 7 Aug. 1958, Jaramillo & al. 921 (holotype, COL-429670!; isotypes, COL-242185!, MA!)" TYPE: Colombia. Santander, Onzaga, vereda de Chaguacá, alto de la laguna de Los Bobos, filo divisorio con Boyacá, 6°19'N, 72°49'W, 7 Aug. 1958, *R. Jaramillo & al.* 921 (holotype, COL-429670!; isotypes, COL-242185!, MA!).

*Perennial herbs*, 7-16 cm tall. *Rootstock* 5.1-9.2 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy (rarely scapiform), not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.5-1.3 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite (cuneate to truncate, with usually 1(3) entire segments); leaf laminas 1-1.3 cm long, 1-1.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.72], polygonal in outline, base cordate, coriaceous, with nerves projected on the abaxial surface, sunken adaxially, covered with abundant, long and stout, eglandular hairs on both surfaces, although restricted to nerves abaxially; segments 5, in 1 plane, middle segment broadly lanceolate, 2.1-2.5 mm wide at the base [ratio segment width at the base/middle segment length = 0.23-0.35], entire; petioles up to 4.8 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1.3 mm long; stipules 2.8-9.2 mm long, 0.8-2.5 mm wide, lanceolate to subulate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 6.4-10.5]; peduncles 15.9-27.6 mm long, with patent, eglandular hairs 0.2-1.3 mm long;

bracteoles 2.5-4 mm long, 0.7-0.8 mm wide, lanceolate, whorled; pedicels 15-25 mm long, with patent, eglandular hairs 0.3-1.2 mm long. Flowers actinomorphic. *Sepals* 4.8-6.8 mm long, 1.6-2.6 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.8 mm long [ratio mucro length/sepal length = 0.08-0.12], with erect-patent, eglandular hairs 0.15-0.9 mm long, mainly on the nerves and margin on the abaxial surface, glabrous adaxially. *Petals* 9.1-12.8 mm long, 4.7-7.4 mm wide, erect-patent, rounded, with claw 0.8-2 mm long, purple, glabrous, rarely with scattered hairs on base of abaxial surface, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3-4.7 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.2-0.5 mm long; anthers 0.8-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.4-5.9 mm long, purple. *Fruit* 14.1-19.8 mm long, reflexed, discharge of seed-ejection type; mericarps 2.3-2.8 mm long, 1.1-1.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with abundant erect-patent, eglandular hairs 0.3-0.6 mm long; rostrum 8.9-12.4 mm long, with a narrowed apex 0.9-1.9 mm long, not twisted, with abundant erect-patent, eglandular hairs 0.6-0.7 mm long; stigmatic remnants 1.8-2.6 mm long, with 5 glabrous lobes. *Seeds* 1.8-2 mm long, 1-1.2 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 538.

*Pollen.* Ornamentation not studied.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower in August.

*Distribution.* This species is endemic to central Colombia (Fig. 539).

*Habitat.* Paramo with *Espeletia* Mutis ex Bonpl.; ca. 3800 m.

**Discussion.** *Geranium jaramilloi* is known only from the type gathering, a

flowering and fruiting collection from northern Colombia. It is most similar to *G. santanderiense* and *G. lainzii*. The three species share an eglandular indumentum, coriaceous leaves, and reflexed fruits. The cauline leaves are small and with few segments, some-

times with only a single lanceolate segment. *Geranium jaramilloi* is sympatric with *G. santanderiense*, which also has cordate leaves. In *G. jaramilloi* the leaves have entire segments and abundant, patent, long, stout, eglandular hairs on both surfaces,

Fig. 538. *Geranium jaramilloi*. a. Habit. b. Leaf, adaxial side. c. Leaf, abaxial side. d. Bracteoles. e. Flower, sepals and petals removed. f. Sepal. g. Petal. h. Staminal filament. i. Fruit. j. Mericarp. k. Seed. (Based on: Jaramillo & al. 921, COL).

Fig. 539. Distribution of *Geranium jaramilloi*.

although restricted to the nerves abaxially, whereas in *G. santanderiense* the leaf segments are 3-lobed, and the laminas are usually glabrous, except for a ciliate margin. The leaves of *G. lainzii* are subtruncate, and have 3-5-lobed segment and scattered hairs near the margin. The fruit rostrum with a narrowed apex also differentiates *G. jaramilloi* from the other two species, in which the rostrum terminates abruptly in the stigmatic remnants. Another notable difference found in herbarium specimens of *G. jaramilloi* is the revolute leaf margin; the basal stipules are usually subulate and adaxially shiny.

**212. *Geranium sebosum*** S.F. Blake, Contr. U.S. Natl. Herb. 20(13): 526. 1924. TYPE LOCALITY: "Type in the U. S. National Herbarium, no. 602198, collected on the Páramo de Timotes, Mérida, Venezuela, altitude 4,000 meters, March, 1910, by Alfred Jahn (no. 5)". TYPE: Venezuela. Mérida, Páramo de Timotes, 8°52'N, 70°48'W, Mar. 1910, A. Jahn 5 (holotype, US-602198!).

*Perennial herbs*, 15-25 cm tall. *Rootstock* 5-8 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, unknown roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.5-2.3 mm long

and patent, glandular hairs 0.3-0.5 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 2.5-3.5 cm long, 3.4-4.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.50-0.60], polygonal in outline, base cordate, not coriaceous,

with nerves not projected, densely hairy, with appressed, eglandular and glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 5-8 mm wide at the base [ratio segment width at the base/middle segment length = 0.37-0.42], 3-5-lobed at the apex [ratio secondary

sinus length/middle segment length = 0.15-0.20]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.5-2.5 mm long and patent, glandular hairs 0.3-0.5 mm long; stipules 5-6 mm long, 2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2-2.3]; peduncles 20-25 mm long, with  $\pm$  patent, eglandular hairs 0.5-2 mm long and patent, glandular hairs 0.5-1 mm long; bracteoles 4-5 mm long, 1 mm wide, lanceolate, whorled; pedicels 10-20 mm long, with  $\pm$  patent, eglandular hairs 0.5-2 mm long and patent, glandular hairs 0.5-1 mm long. Flowers actinomorphic. *Sepals* 4.5-5.5 mm long, ca. 2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.3 mm long [ratio mucro length/sepal length = 0.04-0.05], with  $\pm$  patent, eglandular hairs 0.3-0.5 mm long and  $\pm$  patent, glandular hairs 0.5-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 6-7 mm long, ca. 5 mm wide, erect-patent, rounded or slightly emarginate (notch ca. 0.5 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.2-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4-5 mm long, lanceolate, yellow, glabrous on both surfaces, ciliate on the proximal half, with eglandular hairs 0.3-0.8 mm long and some minute glandular hairs; anthers 0.9-1 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5-6 mm long, purple. *Fruit* 16-18 mm long, erect, discharge of seed-ejection type; mericarps 3-3.5 mm long, 1.5-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.3-0.5 mm long; rostrum 11-12 mm long, without a narrowed apex, not twisted, with patent, eglandular hairs 0.15-

0.6 mm long and patent, glandular hairs 0.5-0.7 mm long; stigmatic remnants ca. 2 mm long, with 5 glabrous lobes. *Seeds* ca. 2.2 mm long, 1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 540.

*Pollen*. *Geranium*-type (Aedo & al. 2003: 98).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to July.

*Distribution*. This species is endemic to western Venezuela (Fig. 541).

*Habitat*. Unknown, probably in *Espeletia* Mutis ex Bonpl. paramo; 3000-4000 m.

*Additional specimens examined*. **Venezuela**. Mérida: Páramo de Timotes, 8°52'N, 70°48'W, 4 July 1934, *Farenholtz s.n.* (B).

*Discussion*. *Geranium sebosum* is characterized by a dense indumentum of long, glandular and eglandular hairs, and can be distinguished from the other species allied with *G. multiceps* by the presence of long glandular hairs on the petioles. Pittier (1929) reported this species from the Páramo de Mucuchíes, Mérida, but the voucher, *Gutzwiller 19* (NY), is *G. velutinum*.

**213. *Geranium stoloniferum*** Standl., Contr. U.S. Natl. Herb. 18: 110. 1916. TYPE LOCALITY: "Type in the U. S. Nation-

al Herbarium, no. 602320, collected in the Páramo de la Cristalina, State of Trujillo, Venezuela, at an altitude of 2,900 meters, December 20, 1910, by Dr. Alfredo Jahn (no. 126)". TYPE: Venezuela. **Discussion.** *Geranium stoloniferum* is known from only two small areas in the southeastern region of the state of Trujillo (Venezuela). It is well characterized by its peculiar habit; from a basal rosette of leaves arises one erect main stem, bearing a well-developed dichasial inflorescence, and one or two herbaceous procumbent stolons. These epigeal stolons arise from the inner part of the rosette and are up to 20 cm long; they have several pairs of opposite leaves (rarely alternate towards the apex) and terminate in a bud. The stolons apparently are produced during one growing season. *Geranium stoloniferum* also has some hypogeous lignified stolons. These arise from the external portion of the rosette, are ramified, and reach a length of 100 cm. They bear some secondary rosettes and terminate in a rosette as well. Such stolon formation may be an adaptive strategy for colonizing wide areas. In fact, individuals of *G. stoloniferum* form extensive patches in the paramo. The stolon formation *G. stoloniferum* is very rare in the genus and is quite unlike the vegetative stems found in *G. holosericeum*, which are entirely covered by stipules. Bono (1996: 554) recorded *G. stoloniferum* from the Páramo de Tamá (Táchira, Venezuela) on limestone (*Steyermark 57348*). Unfortunately, I have not located any specimen of this collection and could not verify the determination.

**Discussion.** Pittier (1929: 180) considered *G. velutinum* to be conspecific with *G. multiceps*, but *G. velutinum*

may be easily separated from that species by the glandular hairs on peduncles, pedicels, and sepals. Unusual specimens with sparse glandular hairs are recognized as *G. velutinum* by the coriaceous or subcoriaceous, flat leaves, velutinous abaxially, and by the reflexed fruits. In contrast, *G. multiceps* has membranaceous, funnel-shaped leaves with short, patent,

eglandular hairs that are restricted to the margin (rarely scattered on both surfaces) and erect fruits. *Geranium velutinum* is also similar to *G. subnudicaule*, which has membranaceous leaves with eglandular hairs on the nerves of the abaxial surface and erect mature fruit. *Geranium velutinum* has a vertical rootstock that is more or less branched and stout,

Fig. 546. *Geranium velutinum* (Based on: a-c, Grande & Aedo 2616, MA; d-e, Grande & Aedo 2618, MA; f-g, Grande & Aedo 2638, MA).

Fig. 547. Distribution of *Geranium velutinum*.

with fusiform roots, whereas in *G. subnudicaule* the vertical rootstock is unbranched and thin, with delicate roots. It is noteworthy that the fruits of *G. velutinum* are reflexed when young, but become erect at maturity. Some collections show variation in vestiture. Usually, *G. velutinum* has patent, glandular hairs (to 1 mm long) on the distal part of stems, inflorescences (peduncles, pedicels, sepals), and the fruit rostrum; however, in some specimens glandular hairs are sparse or absent (e.g., Ruiz Terán & López Figueiras 11, NY). Some collections from Dinira National Park, located between Lara and Trujillo (e.g., Riina & al. 703, MA; Duno & al. 744, MA), have leaves covered abaxially by a sparser indumentum than found in most collections. The collection Luteyn & al. 6025 is a mixed gathering; the sheets at F and U are *G. velutinum*, but the sheet at MO is *G. lindenianum*.

**215. *Geranium subnudicaule* Turcz., Bull. Soc. Imp. Naturalistes Moscou 31(2): 418. 1858. TYPE LOCALITY:** "Sierra Nevada prov. Meridensis Venezuelae, alt. 9000 ped. *Perennial herbs*, 24-83 cm tall. *Rootstock* 2.7-4 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with scattered patent, eglandular hairs 0.1-0.6 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 2-4.8 cm long, 2.4-5.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.82], polygonal in outline, base cor-

date, not coriaceous, with nerves not projected, pilose, with  $\pm$  appressed, mostly eglandular hairs on the adaxial surface, and with eglandular hairs on the nerves of the abaxial surface; segments 5, in 1 plane, middle segment obtriangular, 3.6-12.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.24-0.46], 7-13-lobed in distal half [ratio secondary sinus length/middle segment length = 0.12-0.25]; petioles up to 30 cm long, without abscission zone, terete, not swollen, not deflexed in age, with scattered, patent, eglandular hairs 0.1-0.4 mm long; stipules 6.5-10.2 mm long, 1.8-3.8 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.3-5.8]; peduncles 20-50 mm long, with patent, eglandular hairs 0.15-1.1 mm long and patent, glandular hairs 0.3-0.9 mm long; bracteoles 2-3.5 mm long, 0.5-1.5 mm wide, lanceolate, whorled; pedicels 11-27 mm long, with patent, eglandular hairs 0.15-0.7 mm long and patent, glandular hairs 0.3-1.1 mm long. Flowers actinomorphic. *Sepals* 5.1-8 mm long, 2.1-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.6 mm long [ratio mucro length/sepal length = 0.05-0.12], with  $\pm$  patent, eglandular hairs 0.1-0.7 mm long and erect-patent, glandular hairs 0.3-1 mm long on the abaxial surface, glabrous adaxially. *Petals* 6.8-9 mm long, 2.8-5.5 mm wide, erect-patent, rounded or slightly emarginate (notch 0.3-0.9 mm deep), without claw, purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments 3-4.4 mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.2-0.5 mm long; anthers 0.7-0.9 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.1-6.3 mm long, unknown color. *Fruit* 17.9-21.3 mm long, erect, discharge of seed-ejection type; mericarps 3-3.5

mm long, 1.5-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with scattered, erect-patent, eglandular hairs 0.2-1.2 mm long; rostrum 12-16 mm long, with a narrowed apex 1-2 mm long, not twisted, with erect-patent, eglandular hairs 0.15-1.2 mm long and,

sometimes, patent, glandular hairs 0.5-1 mm long; stigmatic remnants 2-3 mm long, with 5 hairy lobes. *Seeds* 1.9-2.4 mm long, 0.9-1.5 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 548.

*Pollen*. *Geranium*-type (Aedo & al. 2003: 98).

*Chromosome number*. Unknown.

Fig. 548. *Geranium subnudicaule*. a. Habit. b. Detail of leaf, abaxial side. c. Peduncle. d. Sepal. e. Petal. f. Staminal filament. g. Fruit. h. Mericarp. i. Seed. (Based on: a, c, d-f, Funck & Schlim 1127, G; b, Liden 413, K; g-i, Funck & Schlim 1128, BM).

Fig. 549. Distribution of *Geranium subnudicaule*.

**Phenology.** Collected in flower in August.

**Distribution.** This species is endemic to western Venezuela (Fig. 549).

**Habitat.** Unknown; 2500-3000 m.

**Additional specimens examined. Venezuela.** MÉRIDA: Sierra Nevada de Mérida, Aug., *Linden 413* (G, K, MPU, P, W).

**Discussion.** *Geranium subnudicaule* is similar to *G. velutinum*; see that species for a discussion of differences. Surprisingly, *G. subnudicaule* is known from only two old collections gathered near Mérida but without precise locality data (the label of Kew specimen, *Linden 413*, bear the questionable note "Caracas"). The area surrounding the city of Mérida has been frequently visited by botanical collectors; yet, the most recent record of *G. subnudicaule* dates from 1846. As noted in the discussion of *G. velutinum*, more field work is necessary to evaluate fully *G. subnudicaule* and its alliance with *G. velutinum*. The collection *Funck & Schlim 1128*, assigned by Aedo & al. (2003: 121) to *G. subnudicaule*, is *G. meridense*.

Fig. 551. Distribution of *Geranium holosericeum*.

*Discussion.* *Geranium holosericeum* is characterized by the unusual “vegetative stems” and its dichotomously branched, lax inflorescence bearing 2-flowered, loose cymules, even towards the apex of the branches. The current circumscription follows the account of Aedo & al. (2009), a reassessment and elaboration of a previous study. Aedo & al. (2003) emphasized the presence of structures they termed “vegetative stems”. *Geranium holosericeum* produces towards the apex of its branches a kind of bud, sometimes quite long, covered by stipules (usually without petiole remains), which bears a rosette of leaves and an inflorescence. Such structures may be the result of growth of each vegetative period and are also found in some stemless species from the Andes (Aedo & al. 2003). In the publication by Aedo & al. (2003) some collections now assigned to *G. lindenianum* and to *G. schultzei* were included in the circumscription of *G. holosericeum*, but study of newly available additional material allowed for more precise delimitation of species limits.

*Geranium holosericeum* can be distinguished from *G. lindenianum* by its sepals with a shorter mucro. Although with some overlap, additional discriminating characters include the length of sepals, petals, petal hairs, and fruits, which are all shorter in *G. holosericeum*. Field observations showed that both species differ in habit; *G. holosericeum* is an ascending, weak plant that usually leans on the surrounding vegetation, whereas *G. lindenianum* develops an erect and robust stem. Unfortunately, these aspects are difficult to appreciate in the fragments that constitute herbarium specimens. Both species are sympatric in the paramos dividing departments of Santander and Norte de Santander, Colombia. Southward only *G. holosericeum* has been found, but *G. lindenianum* occurs both in Venezuelan paramos and in Sierra de Perijá.

*Geranium schultzei*, for which only one collection (*Hanbury-Tracy 441*, K)

had been seen by Aedo & al. (2003) in their earlier study, is now recognized as an endemic of the Sierra de Santa Marta (Magdalena, Colombia). It is an erect, robust species with an inflorescence similar to that of *G. lindenianum*, but it lacks vegetative stems, and its lanceolate stipules are without a setaceous apex.

Stipule shape also serves distinguish *G. holosericeum* from *G. killipii*, which has a monochasial inflorescence with cymules at each node, unlike the dichasially branched inflorescence of *G. holosericeum*. In some herbarium fragments the inflorescence structure is not apparent, and then the setaceous stipule apex of *G. holosericeum* permits correct identification.

Fig. 553. Distribution of *Geranium schultzei*.

*Discussion.* *Geranium schultzei* was described by Knuth (1930a) as similar to *G. sylvaticum* in habit but up to 1.5 m high. Herbarium specimens of *G. schultzei* generally show robust plants with a strong rootstock from which a single, erect, thick, aerial stem arises that may reach 0.76 cm in diameter and ca. 1 m in length (according to the labels), yet it is herbaceous. *Geranium schultzei* is usually dichotomously branched and bears a large inflorescence with 2-flowered cymules at the first nodes and an aggregate of cymules (pseudoumbels) towards the apex of the branches. The stipules are usually long, glabrous on both surfaces, and remarkably dark reddish. The petals are (12.8)14.8-18.8 mm long. A glandular indumentum covers most of the plant but is only dense in the inflorescence. The leaf indumentum is composed of spreading, usually eglandular hairs that are longer than in *G. lignosum*. As noted above, *G. schultzei* was overlooked in the revision of section *Gracilia* by Aedo & al. (2003) and partially included in *G. holosericeum*, but it was recognized as an endemic of the Sierra Nevada de Santa Marta (Magdalena, Colombia) in the later study (Aedo & al. 2009). The collection *Forero 634* (COL, NY), without basal parts, has more deeply divided leaves than found in other specimens and hairy stipules, but it matches *G. schultzei* otherwise.

The holotype proposed by Knuth (1930a: 2) is lost, and no duplicate was found. Therefore, a neotype collected near the type locality and in agreement with the original description was designated.

**218. *Geranium lindenianum*** Turcz., Bull. Soc. Imp. Naturalistes Moscou 31(2): 418. 1858. TYPE LOCALITY: "Venezuela, Linden coll. u. 1394". TYPE: Venezuela. Páramo del Portachuelo, 8°10'N, 71°54'W, June 1843, *J. Linden 1394* (lectotype, designated by Aedo & al. 2003: 102, KW-001000002 imagen!; isotypes, FI-WI!, K000531427!, LE!, MPU-018502!).

*Perennial shrubby*, 32-80(200) cm tall. *Rootstock* 7.2-10 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, with vegetative stems (6-22 cm long,  $\pm$  horizontal, covered with imbricate stipules, usually without petiole remains), with patent, eglandular hairs 0.5-2.3 mm long and, usually, patent, glandular hairs 0.1-1.2 mm long. *Basal leaves* deciduous, cauline leaves opposite; leaf laminas 4.3-10.4 cm long, 4.4-12 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.80-0.90], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  erect, eglandular hairs and sometimes glandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 5-12.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.23], 8-17-lobed in distal half [ratio secondary sinus length/middle segment length = 0.18-0.34]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.4-2.6 mm long and, usually, patent, glandular hairs 0.2-0.6 mm long; stipules 9-25 mm long, 1.8-5.6 mm wide, lanceolate (with a setaceous apex 1.9-7.7 mm long), free, papery, brownish red, glabrous or with eglandular and, sometimes, glandular hairs on abaxial surface, ciliate on the margin, almost glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1.1-3.4]; peduncles 14-85.2 mm long, with patent, eglandular hairs 0.2-2.1 mm long and patent, glandular hairs 0.3-1.6 mm long; bracteoles 6.9-14.5 mm long, 0.8-2.2 mm wide, lanceolate, whorled; pedicels 11-85 mm long, with patent, eglandular hairs 0.3-1.8 mm long and patent, glandular hairs 0.4-1.6 mm long. *Flowers* actinomorphic. *Sepals* (6.4)8-12.4 mm long, 3.7-5.3 mm wide, lanceolate, smooth, not accrescent, nerves

3-5, mucro (1.2)1.7-2.2 mm long [ratio mucro length/sepal length = 0.15-0.27], with  $\pm$  patent, eglandular hairs 0.4-1.9 mm long and patent, glandular hairs 0.2-1.1 mm long on the abaxial surface,  $\pm$  hairy adaxially. *Petals* (11.2)13.1-19.3 mm long, 6.5-11.5 mm wide, erect-patent, rounded, without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.6-2.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.7-11.3 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.5-1.3 mm long; anthers 1.6-2.8 mm long, blue. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 5.2-12.5 mm long, dark purple. *Fruit* 24.3-35.8 mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.6 mm long, 1.7-2.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with patent, eglandular hairs 0.8-1.3 mm long and, usually,  $\pm$  patent, glandular hairs 0.6-0.9 mm long; rostrum 16-23.6 mm long, with a narrowed apex (1.7)2.2-6.6 mm long, not twisted, with patent, eglandular hairs 0.2-1.2 mm long and patent, glandular hairs 0.4-1.1 mm long; stigmatic remnants 2.7-5 mm long, with 5 glabrous lobes. *Seeds* 2.4-3.1 mm long, 1.4-1.9 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 554, 555.

*Pollen.* *Geranium*-type (Aedo & al. 2009: 228).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from February to November.

*Distribution.* This species ranges from western Venezuela to northern Colombia (Fig. 556).

*Habitat.* Roadside slopes, among rocks, in wet paramo, and among shrubs; 2700-3500 m.

**Discussion.** *Geranium lindenianum* was considered conspecific with *G. holosericeum* by Aedo & al. (2003), but in a later study (Aedo & al. 2009) was recognized as a separate species of the Sierra Perijá and the Venezuelan paramos. The species is more robust than *G. holosericeum* and has an inflorescence like that of *G. schultzei*, but with longer sepals and a longer mucro, longer petals with longer hairs on the adaxial base, and longer fruits than those of *G. holosericeum*. The general appearance of *G. lindenianum* is like that of *G. schultzei*, with a robust, thick, erect stem and a similar inflorescence. Yet, *G. lindenianum* shares with *G. holosericeum* two features never observed in *G. schultzei*: a) vegetative stems, covered with imbricate stipules, usually without petiole remains, and b) lanceolate stipules with a notable setaceous apex. Herbarium specimens of *G. schultzei* are commonly fragments of the apical portion of plants and sometimes difficult to interpret. Field observations show that *G. lindenianum* has a lignified base that is more or less branched. These branches ("vegetative stems") become herbaceous towards the apex and terminate in a zone covered by stipules and a rosette of leaves. From each rosette arises an inflorescence. Well-developed plants lean on neighboring shrubs and may grow to 2 m high.

**The Killipii Group**—This group is characterized by its prostrate to ascending habit, with long stems rooting at nodes, its opposite leaves and its 2-flowered cymules with a long peduncle, arranged in a monochasial inflorescence. It also has distinctive subtomentose buds containing the very young leaves and undeveloped cymules.

**Discussion.** *Geranium killipii* is well characterized by its prostrate to ascending habit, with long stems rooting at nodes, and its 2-flowered cymules with a long peduncle, arranged in a monochasial inflorescence. It also has distinctive subtomentose buds containing the very young leaves and undeveloped cymules, which distinguish it from *G. holosericeum*. Towards the apex of branches young leaves retain

a dense indumentum, which is gradually lost in well-developed leaves. This feature most likely is the basis for Knuth's recognition of *G. hirtum* (1912: 147). *Geranium killipii* may be difficult to distinguish from *G. fallax*, especially when examining poorly prepared herbarium specimens. *Geranium fallax* is an  $\pm$  erect herb that does not root at the nodes, unlike *G. killipii*; it also has longer peduncles, rostrum apex, and petals, although with some overlap. The southern localities of *G. killipii* in Ecuador are separated by more than 800 km from the nearest populations of *G. fallax* in central Peru. The middle leaf segment in specimens of *G. killipii* from central Colombia is usually more lobed (seven or more lobes) than in plants from central Ecuador (ca. five lobes); however, in both areas there are frequent exceptions, and no other consistent difference was found with which to delimit separate taxa. The glandular indumentum is sometimes restricted to the inflorescence and the distal part of the plant, but occasionally reaches the basal part. The inflorescence is composed of 2-flowered cymules with long peduncles (especially towards the base of the plant). Rarely, 1-flowered cymules can be found in some specimens with otherwise 2-flowered cymules.

The holotype of *G. elongatum* was destroyed, and no duplicates were found in other herbaria with holdings of Sodiro collections, but a photograph of the holotype (F, GH, NY) shows a plant that well matches *G. killipii*. *Geranium elongatum* has been considered a synonym of *G. laxicaule*, an endemic to central Peru; see that species for details. The holotype *G. subscandens* is also lost; however, both the type locality and description strongly indicate that this name is a synonym of *G. killipii*. The name *G. trianae*, now listed as a synonym of *G. killipii*, was proposed for an assemblage of Colombian plants determined by Knuth (1912: 147) as *G. hirtum* Willd. ex Spreng., a superfluous name for *G. mexicanum* Kunth, a Mexican species.

**220. *Geranium meridense*** Pittier, J. Wash. Acad. Sci. 19: 178. 1929. TYPE LOCALITY: "Mérida: Páramos de Sto. Domingo and Chachopo, 3100 m., flowers Sept. 14, 1922 (Dr. A. Jahn 1130a, Type)". Las Mesitas, 9°4'N, 70°29'W, 30 July 2010, *Grande & Aedo* 2469 (MA).

*Discussion.* *Geranium meridense* is similar to *G. killipii* in its prostrate to ascending habit and subtomentose buds. The leaves of *G. meridense* are shorter than in *G. killipii*, and the middle segment has fewer lobes. *Geranium meridense* differs also in its shorter peduncles, sepals, and petals, although with some overlap. These characters and the allopatric distribution support recognition of *G. meridense* as separate from *G. killipii*. In *G. meridense* the glandular indumentum is restricted to the inflorescence and is usually present on sepals, sometimes on pedicels, and more rarely on peduncles. The fragmentary spec-

imen *Fernández & Bracamonte* 1106 (PORT) has the short petals and peduncles typical for *G. meridense*, but has leaves with 7-9 lobes. It is provisionally included in *G. meridense*.

### Other species from South America

**221. *Geranium lignosum*** R. Knuth, Repert. Spec. Nov. Regni Veg. 28: 10. 1930. TYPE LOCALITY: "Colombia: Charakterpflanze der Paramos, Siminchuena, 3200 m (A. Schultze, Reise in die Sierra Nevada de Santa Marta a. 1928 n. 1232 -- Typus in herb. Berol.). -- Fruchtend März". TYPE: Colombia. Magdalena, Sierra Nevada de Santa Marta, Siminchuena, 1928, A. Schultze 1232 (holotype, B destroyed). Colombia. Magdalena, Sierra Nevada de Santa Marta, 10°45'N, 73°40'W, June 1844, *W. Purdie? s.n.* (neotype, designated by Aedo & al. 2003: 108, K!).

*Perennial shrubby*, ca. 50 cm tall. *Rootstock* and roots unknown. *Stem* erect, leafy, not rooting at nodes, stolons absent, with lateral branches having stipules groups and rosettes of leaves, with patent to retrorse, eglandular hairs 0.5-1.2 mm long. *Basal leaves* unknown, cauline leaves opposite; leaf laminae 2-3.5 cm long, 2.2-4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.70-0.90], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with  $\pm$  appressed, eglandular hairs on the adaxial surface and usually velutinous abaxially; segments 5, in 1 plane, middle segment rhombic, 2-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.12-0.23], 6-13-lobed in distal half [ratio secondary sinus length/middle segment length = 0.16-0.43]; petioles up to 9 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.1-1

mm long; stipules 6-9 mm long, 1.5-2 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, almost glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2-2.2]; peduncles 27-90 mm long, with abundant retrorse to patent, eglandular hairs 0.1-1.2 mm long and scattered, patent, glandular hairs 0.3-0.6 mm long; bracteoles 3.3-7.9 mm long, 0.6-1.5 mm wide, lanceolate, whorled; pedicels 6-35 mm long, with some patent, eglandular hairs 0.1-0.8 mm long and abundant patent, glandular hairs 0.2-0.6 mm long. Flowers actinomorphic. *Sepals* 6.2-10 mm long, 2.2-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.6-1.5 mm long [ratio mucro length/sepal length = 0.10-0.17], with  $\pm$  patent, eglandular hairs 0.2-1.5 mm long and erect-patent, glandular hairs 0.2-0.7 mm long on the abaxial surface, hairy adaxially. *Petals* 10-14.2 mm long, 5.4-9 mm wide, erect-patent, rounded, with claw ca. 1 mm long, dark purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the margin, with hairs 0.9-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7-10 mm long, lanceolate, dark purple, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.8-1.4 mm long; anthers 1.3-2.3 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 7.9-9.5 mm long, dark purple. *Fruit* 25-33 mm long, erect, discharge of seed-ejection type; mericarps 3-4.5 mm long, 2-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.5-1.4 mm long; rostrum 21-24.5 mm long, with a narrowed apex 2.4-3 mm long, not twisted, with abundant patent, eglandular hairs 0.2-0.9 mm long and glandular hairs 0.3-0.5 mm long; stigmatic remnants 4-4.3 mm long, with 5 glabrous lobes. *Seeds* ca.

1.9 mm long, 1 mm wide, finely reticulate, uniformly colored, blackish, glabrous. Cotyledons with entire margin. Fig. 563.

*Pollen.* *Geranium*-type (Aedo & al. 2003: 99).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower in May.

*Distribution.* This species is endemic to northern Colombia (Fig. 564).

*Habitat.* Montane rain forests; 3300-4000 m.

*Additional specimens examined. Colombia.* MAGDALENA: vicinity río Mamancanaca, 10°43'N, 73°39'W, 26 May 1977, *White & Alverson 600* (COL, MO, NY); valley of río Yeboimeina, 10°44'N, 73°39'W, 26 May

1977, *White & Alverson 601* (COL, HUA, NY); Santa Marta, 10°45'N, 73°40'W, 1845, *Purdie s.n.* (GH); Sierra Nevada, Santa Marta, 10°45'N, 73°40'W, 1880, *Simons s.n.* (BM).

*Discussion.* *Geranium lignosum* can be distinguished from all other species of *Geranium* from Colombia by its woody fertile shoots, its short lateral branches bearing stipules groups and persistent rosettes of leaves (usually velutinous abaxially), and its dark purplish petals and staminal filaments. Some herbarium specimens include only the lateral rosettes, which hinders proper identification, if the label does not indicate the shrubby habit. The leaves of *G. lignosum* have a short, close, and ± appressed indumentum of eglandular hairs. *Geranium lignosum* is a restricted endemic of the Sierra Nevada de Santa Marta (Magdalena, Colombia). Knuth (1930a: 10), who apparently had only a fragmentary specimen available, described this species as a shrub ca. 50 cm high, but more recently collected material has short branches about 35 cm long. A label accompanying *White & Alverson 600* (COL) indicates "Shrub sprawling over edge of streambank, ... forming a dense bush", which suggests that *G. lignosum* is a more robust plant than thought by Knuth. The description of *G. lignosum* presented here is emended in some details from that published by Aedo & al. (2003), but additional collections are need-

Fig. 563. *Geranium lignosum*. a. Flowering branch. b. Detail of leaf, adaxial side. c. Peduncle. d. Sepal. e. Petal. f. Staminal filament. g. Fruit. h. Mericarp. i. Seed. (Based on: a, *Purdie? s.n.*, June 1844, K; b-i, *Simons s.n.*, 1880, BM).

ed to assess the morphology of this species. Among sympatric species, *G. schultzei* could be mistaken for *G. lignosum* because of its robust habit, but it has longer leaves with  $\pm$  patent hairs and more lobes per segment, longer stipules, a sympodial inflorescence with an aggregate of cymules towards the apex of the branches, and longer petals than *G. schultzei*. Another species with a robust habit that grows in northern Colombia is *G. lindenianum*, which differs from *G. lignosum* by its longer leaves with  $\pm$  patent hairs, longer stipules with a setaceous apex, a sympodial inflorescence with an aggregate of cymules towards the apex of the branches, longer sepals with a long mucro, and longer petals with long hairs.

The lectotype proposed by Knuth (1930a: 10) is lost, and no duplicate was found. Therefore, a neotype collected near the type locality and in agreement with the original description was designated.

**222. *Geranium matucanense* R.** Knuth, Repert. Spec. Nov. Regni Veg. 28: 5. 1930. TYPE LOCALITY: "Peru: Matucana, 2400 m. (Macbride et Featherstone a. 1922 n. 462 in Exp. Capt. Marshall Field Fund -- Typus in herb. Field Museum n. 516996!). --Blühend April bis Mai". TYPE: Peru. Lima. Matucana, 11°51'S, 76°24'W, 1922, J.F. Macbride & W. Featherstone 462 (holotype, F-516996!; isotype, G-00439760!).

*Perennial herbs*, 22-46 cm tall. *Rootstock* 10-22 mm in diameter,  $\pm$  vertical, unknown roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.7 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas 1.8-4.4 cm long, 2-5.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.83-0.85], polygonal in outline, base cordate, not coria-

ceous, with nerves not projected, densely hairy, with  $\pm$  appressed, eglandular hairs on the adaxial surface, and lanuginose abaxially; segments 5, in 1 plane, middle segment rhombic, 1.2-5.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.08-0.19],

3-7(9)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.26-0.48]; petioles up to 19 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.8 mm long; stipules 2.9-5.9 mm long, 1.4-4.8 mm wide,

lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, almost glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.3-4]; peduncles 50-114(131) mm long, with retrorse, appressed, eglandular hairs 0.3-0.7 mm long; bracteoles 4.1-7.6 mm long, 0.5-1.3 mm wide, lanceolate, whorled; pedicels 17-58.9 mm long, with retrorse, appressed, eglandular hairs 0.3-0.7 mm long. Flowers actinomorphic. *Sepals* (8.1)9-10.3(10.8) mm long, 2.6-4.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.1)1.3-2(2.9) mm long [ratio mucro length/sepal length = 0.12-0.33], with antrorse,  $\pm$  appressed, eglandular hairs 0.4-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (14.1)20-22(27.2) mm long, 7.5-12.8 mm wide, erect-patent, rounded or slightly emarginate (notch 0.4-1 mm deep), without claw, purple, hairy on both surfaces, mainly on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.5-1.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 8.7-12.5 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 1-1.6 mm long; anthers 2-2.8 mm long, dark purple. Nectaries 5, hemispheric, with a tuft of hairs at the top,

dorsally glabrous. *Gynoecium* 9-16.1 mm long, dark purple. *Fruit* 31.3-33.6 mm long, erect, discharge of seed-ejection type; mericarps 4.2-5.6 mm long, 1.6-2.9 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  antrorse, appressed, eglandular hairs 0.5-0.8 mm long; rostrum 23.2-25.7 mm long, with a narrowed apex 6.3-8.5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.4 mm long; stigmatic remnants 2.5-2.8 mm long, with 5 glabrous lobes. *Seeds* 2.6-3.4 mm long, 1.4-2.3 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons not studied. Fig. 565.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to December.

*Distribution*. This species ranges through central Peru (Fig. 566).

*Habitat*. Rocky and shrubby slopes; 2650-3300 m.

*Additional specimens examined*. **Peru**. Peru, *Dombey s.n.* (P). ANCASH: Huarí, Yanas, distr. Huacchis, 9°9'S, 76°47'W, 18 Feb. 2005, *Cano & al.* 14970 (MA). *Discussion*. *Geranium matucanense* shares a similar inflorescence structure with *G. mutisii*, but the cymules are 2-flowered and have a long peduncle, which is a useful distinguishing character for *G. matucanense*. The indumentum of retrorse, appressed hairs on stems, petioles, and inflorescences is also similar in both species. No glandular hairs are present in *G. matucanense*, but *G. paramicola*

and *G. mutisii* bear glandular hairs at least on sepals and pedicels. *Geranium matucanense* also differs from *G. mutisii* in its petiolate leaves and its longer sepals, petals, and fruits. The hairs of staminal filaments are noticeably longer in *G. matucanense* than in *G. paramicola* and *G. mutisii*.

**223. *Geranium mutisii*** Aedo, J. Torrey Bot. Soc. 136: 289, 290 fig. 1. 2009. TYPE LOCALITY: "Colombia. La Guajira, Sierra Nevada de Santa Marta, laguna Sabaca, nacimiento del río San Miguel, 10°40'N, 73°01'W, 3900 m, 16 Aug 1986, Cuadros & Gentry 2709 (holotype, MA-626646!; isotype, MO!)". TYPE: Colombia. La Guajira, Sierra Nevada de Santa Marta, laguna Sabaca, nacimiento del río San Miguel, 10°40'N, 73°00'W, 16 Aug. 1986, *H. Cuadros & A.H. Gentry* 2709 (holotype, MA-626646!; isotype, MO-2235217!).

*Perennial herbs*, 30-61 cm tall. *Rootstock* and roots unknown. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long. *Basal leaves* unknown, cauline leaves opposite; leaf laminae 2.6-5.1 cm long, 2.4-7.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.86-0.91], polygonal in outline, base cordate, not coriaceous, with nerves not projected, densely hairy, with  $\pm$  appressed, eglandular hairs on the adaxial surface, and lanuginose abaxially; segments 5, in 1 plane, middle segment rhombic, 1.3-4.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.04-0.09], 3-7-lobed in distal half [ratio secondary sinus length/middle segment length = 0.41-0.52]; petioles usually absent, rarely present, without abscission zone, with retrorse, appressed, eglandular hairs 0.3-0.4 mm long; stipules 3.5-6.6 mm long, 1.5-4.4 mm wide, lanceolate, free or connate (at least at the base), pa-

Fig. 568. Distribution of *Geranium mutisii*.

ever, it has an erect habit, retrorse appressed hairs on stems and the fruit rostrum, and a longer sepal mucro. Its leaves are more deeply divided; the segments are narrower than in *G. paramicola* and 3-lobed [segments are (5)6-11-lobed in *G. paramicola*]. The cauline leaves of *G. mutisii* are sessile, whereas in *G. paramicola* the petioles decrease in length towards the apex; no basal leaves of *G. mutisii* were seen. The inflorescence structure is also differs in these species. *Geranium mutisii* has a dichasial cyme with monochasial branches and 2-flowered cymules, borne solitary or in aggregates at the apex of each branch; the cymules are sometimes 1-flowered. In *G. paramicola* the inflorescence is a monochasial cyme with 2-flowered, solitary cymules. The nectaries of *G. mutisii* have a tuft of hairs at the apex, but are glabrous in *G. paramicola*. The stipules of *G. mutisii* are usually connate, at least at the first and second nodes. This feature is found otherwise only in some species from the Himalayas and Africa of subg. *Geranium*.

**224. *Geranium paramicola*** R. Knuth, Repert. Spec. Nov. Regni Veg. 40: 216. 1936. TYPE LOCALITY: "Colombia: Páramos der Sierra de Santa Marta, bei Dibulla, 3850 m (Seifríz a. 1932 n. 458 - Typus in U. St. Nat. Herb. n.

1572281!)" TYPE: Colombia. La Guajira, Páramos der Sierra de Santa Marta, bei Dibulla, 10°50'N, 73°28'W, July 1932, W. Seifríz 458 (holotype, US-1572281!).

*Perennial herbs*, 9-41 cm tall. *Rootstock* ca. 7 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, unknown roots. *Stem* ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-0.7 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas 1.9-5 cm long, 2.9-6.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.76-0.82], polygonal in outline, base cordate, not coriaceous, with nerves not projected, densely hairy, with ± erect, eglandular hairs on the adaxial surface, and lanuginose abaxially; segments 5, in 1 plane, middle segment rhombic, 2.1-5.6 mm wide at the base [ratio segment width at the base/middle segment length = 0.14-0.18], (5)6-11-lobed in distal half [ratio secondary sinus length/middle segment length = 0.36-0.51]; petioles up to 11.5 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.5-0.8 mm long and, sometimes, scattered, patent, glandular hairs 0.3-0.5 mm long; stipules 3.1-5 mm long, 0.7-1.4 mm wide, lanceolate, free, papery, brownish red, with long eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.1-5.8]; peduncles 19-145 mm long, with patent, eglandular hairs 0.2-0.7 mm long and, usually, patent, glandular hairs 0.3-0.6 mm long; bracteoles 1.9-3.8 mm long, 0.5-0.6 mm wide, lanceolate, whorled; pedicels 21-32 mm long, with patent, eglandular hairs 0.2-0.9 mm long and patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* 6.1-8.3 mm long, 2.3-3 mm wide, lanceolate, smooth, not accrescent, nerves 3,

mucro 0.4-0.6 mm long [ratio mucro length/sepal length = 0.06-0.11], with ± patent, eglandular hairs 0.4-0.7 mm long and patent, glandular hairs 0.3-0.7 mm long on both surfaces. *Petals* 9.8-14.1 mm long, 5.9-9.2 mm wide, erect-patent, rounded, without claw, purple, with scattered hairs on the base of the adaxial surface, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4-5.1 mm long, lanceolate, unknown color, pilose on the abaxial surface, ciliate on the proximal half, with eglandular hairs 0.4-0.6 mm long; anthers 0.7-1.4 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.8-5.7 mm long, unknown color. *Fruit* 20.1-23.4 mm long, erect, discharge of seed-ejection type; mericarps 3.3-3.8 mm long, 1.4-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.3-1 mm long; rostrum 13.4-17.1 mm long, with a narrowed apex 1.2-2 mm long, not twisted, with ± patent, eglandular hairs 0.2-0.8 mm long; stigmatic remnants 1.8-3.2 mm long, with 5 glabrous lobes. *Seeds* 2-2.9 mm long, 1.1-1.9 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons not studied. Fig. 569.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to October.

*Distribution*. This species is endemic to northern Colombia (Fig. 570).

*Habitat*. Paramos; 3200-4500 m.

*Additional specimens examined*. **Colombia**. MAGDALENA: Sierra Nevada, 1829, Simons s.n. (BM); Sierra Nevada de Santa Marta, Duriameina, 10°31'N, 73°42'W, 18 Aug. 1946, Foster & al. 1547 (COL, GH, MA); Sierra Nevada de Santa Marta, SE slopes, Hoya del río Donachui, below Dirincune Sabana, 10°43'N, 73°30'W, 29 Sep. 1959, Cuatrecasas & Romero 24489 (COL); Sierra Nevada de Santa Marta, valle del río Donachuy, camino Corisa-Nabona lake, 10°44'N, 73°42'W, 15 Oct. 1958, Hammen 1167 (COL).

**Discussion.** *Geranium paramicola* has an ascendant habit and is well characterized by its densely hairy leaves, which are lanuginose abaxially. Among South American species of *Geranium* such leaf vesture is also found in some stemless species from the Andes (all with 1-flowered cymes) and in other species allied

with *G. paramicola*. Additionally, *G. paramicola* has patent, eglandular hairs on stems, stipules, and bracteoles. A dense glandular indumentum covers sepals and pedicels, and sometimes also peduncles. The fruit rostrum and the mericarps have  $\pm$  patent, eglandular hairs in all specimens examined, including the type.

Knuth's statement (1936: 216) "Rostrum dense glandulosum" is an error.

**IIb. *Geranium* sect. *Paramensia* R.** Knuth in Engl., Nat. Pflanzefam. ed. 2, 19a: 55. 1931. TYPE: *Geranium jahnii* (designated by Knuth 1931: 55).

*Leaves* with an abscission zone between lamina and petiole. *Stipules* ovate to lanceolate, entire, sometimes with a very short bifid apex. *Mericarps* with a basal callus.

Similarities between the sect. *Paramensia* and sect. *Neurophyllodes* (endemic to Hawaii) were already noted by (Standley 1915: 600). Both sections have a shrubby habit and unlobed, parallel-veined leaves rather than a herbaceous habit and palmate leaves typical of the genus. The most noteworthy feature shared by both groups is the presence of an abscission zone (at the apex of the petiole in the sect. *Paramensia* and at the base of the petiole in the sect. *Neurophyllodes*). This highly specialized feature, otherwise unknown in *Geranium*, suggests a common ancestry (Standley 1915: 600; Aedo & al. 2002: 213). The strong resemblance between the leaves of *G. jahnii* and *G. cuneatum* (of sect. *Neurophyllodes*) is also remarkable; they are obtriangular in outline and have teeth at the apex.

**225. *Geranium exallum*** H.E. Moore, Brittonia 13(2): 142, 143 fig. 1A. 1961.

TYPE LOCALITY: "Ecuador: Prov. Azuay--'Oriente' Border: Eastern Cordillera, between Oña and the Río Yacuambi, 10,000-11,200 ft alt., 10-19 Sep 1945, F. Prieto 279 (Holotype, NY; isotype BH)". TYPE: Ecuador. Azuay, between Oña and the Río Yacuambi, 3°27'S, 79°06'W, 10-19 Sep. 1945, F. Prieto 279 (holotype, NY-00468265!; isotypes, BH!, K!, U-0002233 image!, US-00100883 image!).

Perennial shrubby, 6-20 cm tall. Rootstock 2-4 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. Stem erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, glabrous, densely clothed with imbricate persistent stipules and petioles. Basal leaves deciduous, cauline leaves alternate; leaf lamina 0.8-1.1 cm long, 0.2-0.3 cm wide, not peltate, entire, lanceolate in outline, base cuneate, coriaceous, with nerves not projected, glabrous on both surfaces, with antrorse, eglandular cilia 0.1-0.3 mm long on the margin; segments 1; petioles up to 0.45 cm long, with an abscission zone between lamina and petiole, terete, not swollen, not deflexed in age, glabrous or with scattered, retrorse, eglandular hairs 0.1-0.2 mm long; stipules 2.1-4 mm long, 0.5-0.7 mm wide, lanceolate, free, papery, brownish red, glabrous on both surfaces, with antrorse, eglandular hairs 0.1-0.2 mm long on margin. Cymes 1-flowered, solitary at the end of each branch [ratio cymule length/leaf length = 1.4-3.4]; peduncles 7-13 mm long, with retrorse, appressed, eglandular hairs 0.2-0.4 mm long; bracteoles 5-7.5 mm long, 0.7-1 mm wide, linear-lanceolate, opposite; pedicels 3.4-19 mm long, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. Flowers actinomorphic. Sepals 7.5-10 mm long, 2.5-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.8-1.4 mm long [ra-

tio mucro length/sepal length = 0.13-0.17], with ± patent, eglandular hairs 0.2-0.7 mm long on both surfaces (mainly on nerves and margin). Petals 11-14.2 mm long, 6-7.8 mm wide, erect-patent, rounded, without claw, purple, glabrous. Stamens 10, both whorls bearing anthers; filaments

4-5.2 mm long, lanceolate, yellow, glabrous except for a few marginal hairs 0.2-0.4 mm long; anthers 1-1.5 mm long, yellow. Nectaries 5, hemispheric, glabrous. Gynoecium 4-5 mm long, yellow. Fruit ca. 17 mm long, erect, discharge of seed-ejection type; mericarps ca. 3.2 mm long, 1.5

mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callos, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.7 mm long; rostrum ca. 11 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular hairs 0.1 mm long; stigmatic remnants ca. 3 mm long, with 5 glabrous lobes. *Seeds* ca. 2.2 mm long, 1.2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 571, 572.

*Pollen.* *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from September to November.

*Distribution.* This species is endemic to southern Ecuador (Fig. 573).

*Habitat.* Rocky outcrops and marshy places in grass paramo with *Pinus* L. plantation, disturbed and burning; 2700-3100 m.

*Additional specimens examined.* **Ecuador.** CAÑAR: Cordillera Cordoncillo, El Quingueado (Saraguro), along road from Babes (ca 2 km E of Urdaneta) towards 28 de Mayo, 3°34'S, 79°6'W, 20 Nov. 2010, Sklenář & al. 13027 (PRC). LOJA: Cordillera Cordoncillo, along road from Babes, ca. 2 km E of Urdaneta, towards 28 de Mayo, 3°34'S, 79°6'W, 10 Nov. 2018, Sklenář & al. 15822 (MA).

*Discussion.* *Geranium exallum* is easy to differentiate from other species of *Geranium* by its coriaceous, lanceolate, entire leaves, which, as also noted by Moore (1961: 141), is a unique condition in the genus. This species resembles most closely *G. jahnii* in its shrubby habit, its stems densely clothed with imbricate persistent stipules and petioles, and its leaves with an abscission zone between the lamina and the petiole. *Geranium jahnii* differs in its obtriangular glabrous leaves with a tridentate apex and pedicels with glandular hairs; *G. exallum* has lanceolate, entire leaves with marginal cilia and pedicels without glandular hairs. Additionally, the stipules have a setaceous apex in *G. jahnii*, which is not found in *G. exallum*. The two species constitute the sect. *Paramensia*, which appears to be a well-supported natural group (Aedo & al. 2002).

**226. *Geranium jahnii*** Standl., J. Wash. Acad. Sci. 5: 601. 1915. TYPE LOCALITY: "Type in the U.S. National Herbarium, no. 602229, collected on the Páramo del Jabón, State of Trujillo, Venezuela, altitude 3000 to 3200 meters, October 2, 1910, by Dr. Alfredo Jahn (no. 34)". TYPE: Venezuela. Trujillo, Páramo del Jabón, 9°53' N, 70°30' W,

2 Oct. 1910, A. Jahn 34 (holotype, US-602229!; isotype, VEN-5308 image!).

*Perennial shrubby*, 8-13 cm tall. *Rootstock* 3-4 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, glabrous, densely clothed with imbricate persistent stipules and petioles. *Basal leaves* deciduous, cauline leaves alternate; leaf laminas 6.2-12.5 cm long, 2-4.3 cm wide, not peltate, entire with tridentate apex [ratio main-sinus length/middle segment length = 0.15-0.19], obtriangular in outline, base cuneate, coriaceous, with nerves projected on the abaxial surface, glabrous; segments 3, in 1 plane, middle segment lanceolate, entire; petioles up to 0.5 cm long, with an abscission zone between lamina and petiole, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.1-0.2 mm long; stipules 5.5-7.1 mm long, 0.7-1 mm wide, lanceolate (with a setaceous apex 1.3-2.5 mm long), free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Cymules* 1-flowered, grouped at the end of each branch [ratio cymule length/leaf length = 1.4-2.8]; peduncles 3.8-9.7 mm long, with patent, eglandular hairs 0.1-0.3 mm long; bracteoles 3-4.6 mm long, 0.5-0.7 mm wide, linear-lanceolate, whorled; pedicels 3.4-25 mm long, with patent, eglandular hairs 0.1-0.6 mm long and, usually, patent, glandular hairs 0.4-0.6 mm long. Flowers actinomorphic. *Sepals* 6.3-7 mm long, 2-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-1 mm long [ratio mucro length/sepal length = 0.12-0.16], with patent, eglandular hairs 0.3-0.7 mm long and patent, glandular hairs 0.4-0.7 mm long on the abaxial surface and margin, glabrous adaxially. *Petals* 10.3-13 mm long, 5-8 mm wide, erect-patent, rounded, with claw ca. 2 mm long, purple, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.2-0.5 mm

long. *Stamens* 10, both whorls bearing anthers; filaments 3.5-4.8 mm long, lanceolate, yellow, glabrous except for a few marginal hairs 0.2-0.7 mm long; anthers 0.8-1.1 mm long, unknown color. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 4-4.8 mm long,

yellow. *Fruit* 14-17.2 mm long, erect, discharge of seed-ejection type; mericarps 3-3.1 mm long, 1.7-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with antrorse,

± appressed, eglandular hairs 0.1-0.4 mm long; rostrum 10-11.7 mm long, without a narrowed apex, not twisted, with ± patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.8-1 mm long, with 5 glabrous lobes. *Seeds* ca. 2.4 mm long, 1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 574, 575.

*Pollen*. *Geranium*-type (Aedo & al. 2002: 217).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to August.

*Distribution*. This species is endemic to northwestern Venezuela (Fig. 576).

*Habitat*. Wet places among dwarf shrubs; 3000-3350 m.

*Additional specimens examined*. **Venezuela**. TRUJILLO: Parque Nacional Dinira, fila hacia el Pico Cendé, 9°31'N, 70°6'W, 15 Aug. 1999, Riina & al. 748 (MA); Carache, Parque Nacional Dinira, arriba de Mesa Arriba, Pico Cendé, ladera NW, 9°32'N, 70°7'W, 2 Apr. 1999, Duno & Riina 781 (MA); Parque Nacional Dinira, Páramo de Jabón, 9°34'N, 70°7'W, 14 Aug. 1999, Riina & al. 597 (MA).

*Discussion*. *Geranium jahnii* differs from all other New World species by its distinctive obtriangular, tridentate leaves with an abscission zone between the lamina and the petiole. The differences and similarities between *G. jahnii* and *G. exallum* are addressed in the discussion under the latter species.

**II.c *Geranium* sect. *Neurophyllodes*** A. Gray, U.S. Expl. Exped., Phan. 1: 310. 1854. *Neurophyllodes* (A. Gray) O. Deg., Fl. Hawaiiensis: 171. 1937. TYPE: *Geranium arboreum* A. Gray (designated by Knuth 1912: 47).

*Petiole* with an abscission zone at base. *Stipules* ovate to lanceolate, entire, sometimes with a very short bifid apex. *Mericaeps* with a basal callus.

**227. *Geranium arboreum*** A. Gray, U.S. Expl. Exped., Phan. 1: 315, tab. 31. 1854, 1856. *Neurophyllodes arborea* (A. Gray) O. Deg., Fl. Hawaiiensis, Fam. 171. 1937. TYPE LOCALITY: "Hab. Eastern part of the island of Maui, Sandwich Islands; near the upper border of the forest, at about the elevation of 6000 feet". TYPE: U.S.A. Hawaii. Maui Is., 20°43'N, 156°12'W, 1840, W. Brackenridge & al. s.n. (lectotype, designated by St. John 1985: 571, US!; isolectotypes, K!, NY!, P!, PH).

*Shrub*, 180-400 cm tall. *Rootstock* and roots unknown. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.5-1 mm long (on young branches mainly). *Basal leaves* unknown, cauline leaves alternate; leaf laminae (2.6)2.8-5.4(6.5) cm long, 1.5-4.6 cm wide, not petate, entire with serrate margin [with 5-21 teeth on each side, almost to the base], ovate in outline, base cordate to subcordate, coriaceous, with nerves not projected, pilose, with ± patent, eglandular hairs on both surfaces; segments 1; petioles up to 2.2 cm long, with an abscission zone between petiole and stipule, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.6-1.2 mm long; stipules 5.5-11.7 mm long, 1.5-2.3 mm wide, lanceolate (with a setaceous apex 2.1-5.8 mm long), sheathing, connate at the base, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, grouped in 2-6-flowered cymes at the end of each brachyblast [ratio cymule length/leaf length = (0.8)1.1-1.4]; peduncles 7.8-12.4 mm long, with patent, eglandular hairs 0.6-1.2 mm long; bracteoles 3-5.1 mm long, 0.6-1.2 mm wide, linear-lanceolate, subopposite, overlapping at base on one side of the peduncle, exposing the opposite part. Flowers zygomorphic. *Sepals* (10.5)11-12.1(13.5) mm long, 2.7-3.9

mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1.5-3.8 mm long [ratio mucro length/sepal length = 0.14-0.32], with  $\pm$  patent, eglandular hairs 0.3-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (16.4)17-22.5 mm long, 3.8-7.5 mm wide, arcuate, the

upper 3 erect (with revolute apex), the lower ones reflexed, rounded, without claw, reddish, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.4-1.1 mm long. *Stamens* 10, both whorls bearing anthers; filaments (11.3)17-21 mm long, linear-lanceolate, with

a dark purple apex, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-1.4 mm long; anthers 1.7-2.2 mm long, dark purple. Nectaries 5,  $\pm$  hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 13.4-19.4 mm long, dark purple. *Fruit* 34.5-47.2 mm long, erect, discharge of seed-ejection type; mericarps 3.4-4.3 mm long, 1.6-2.3 mm wide, without a strand of fibers, not compressed at the apex, smooth (with 1-2 transverse veins at apex), without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.6-1.4 mm long; rostrum 28.8-35.4 mm long, with a narrowed apex 12.8-16.1 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.3-0.8 mm long; stigmatic remnants 2.4-3.8 mm long, with 5 glabrous lobes. *Seeds* 2.2-2.7 mm long, 1.3-1.5 mm wide, reticulate-sinuuous, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 577.

*Pollen*. *Geranium*-type.

*Chromosome number*.  $2n = c. 50$ .

*Phenology*. Collected in flower from April to October.

*Distribution*. This species is endemic to southeastern of Maui Is., Hawaii (Fig. 578).

*Habitat*. Steep sides of moist ravines with shrubby vegetation, sometimes on plantations of *Eucalyptus* L'Hér.; 600-2450 m.

*Discussion.* The endemic Hawaiian species of *Geranium* have sometimes been treated as belonging to a separate genus because of their singular features: shrubby habit, leaves with parallel veins, and petioles with an abscission line at the base. Among them, *G. arboreum* is unique in the genus because of its zygomorphic reddish corolla, which is probably an adaptation to bird pollination (Carlquist 1980: 135). It is also interesting to note that it is the most robust species of the genus. According to the original description, the trunk is up to 10 cm or more in diameter, and attains a height of 4 meters. On herbarium sheets only small fragments of flowering or fruiting branches are preserved. Thus, little information is available about the basal or underground parts or about the early stages of its development. The indument consists of short, spreading, eglandular hairs, scattered on young branches, leaves, and inflorescence. The hairs persist on woody branches but they progressively disappear with branch age. Each pair of stipules is fused at the base to form a sheath that surrounds the next portion of the branchlet. At the opposite extreme, each stipule ends in a narrow tip. The abscission line of the petiole is at its base, just at the junction of the petiole and the stipules. Thus, when the petioles (and consequently the leaf laminae) fall, the branchlets acquire a unique aspect because of the sheathing, persistent stipules. Along branches some floriferous branchlets can occur. These partial inflorescences are 2-6-flowered cymes in a complex structure. On the basal part of these inflorescences some axillary leaves occur. One single flowered cymule is usually borne on each node. It is interesting to note that on each peduncle there are two bracteoles. They are not sheathing but overlap at the base on one side of the peduncle to expose the opposite part. In other species of *Geranium* with 1-flowered cymules, the bracteoles are perfectly opposite. All nodes of the inflorescence, i.e.,

base of peduncle and partial branchlets, have abscission lines, which may contribute to seed dispersal as a complementary mechanism of autochory, superposed on the ballistic seed-ejection system of this *Geranium*. The shape of the nectaries is difficult to ascertain in dried material, but they seem to differ from the hemispherical ones in most species of the genus. The nectariferous area appears to be a slight depression with two lateral edges, usually with scattered hairs. The stamens are slightly curved and a bit shorter than the petals. They are exerted beyond the throat because the apex of the petals is more or less reflexed. The stamens appear to be accrescent in fruit. The fruit of *G. arboreum* is typical of *Geranium* subg. *Geranium*, presenting the seed-ejection type of discharge. The fruit rostrum has a very long, glabrous, narrowed apex not present in the remaining endemic species of Hawaii. It is curious to note that *G. palmatum*, an endemic from the island of Madeira in the Atlantic Ocean, also has very long stamens exerted far beyond the throat, a slightly zygomorphic corolla, and a fruit rostrum with a long narrowed apex. *Geranium palmatum*, however, belongs to subg. *Robertium*, characterized by the carpel-projection type of discharge.

**Shrub**, 100-200(300) cm tall. **Rootstock** and roots unknown. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with antrorse, appressed, eglandular hairs 0.1-0.2 mm long (on young branches mainly). **Basal leaves** unknown, cauline leaves alternate; leaf laminae (2.2)3.1-5.5(6.3) cm long, 1.3-3.7 cm wide, not peltate, entire with serrate margin [with (1)4-14 teeth on each side, usually almost to the base but at least 1/3 from apex], ovate to elliptic, rarely obovate in outline, base cuneate,  $\pm$  coriaceous, with nerves not projected, usually glabrous except on the nerves of the adaxial surface (rarely with sparse hairs to moderately sericeous) and sericeous

abaxially; segments 1; petioles up to 2.4 cm long, with an abscission zone between petiole and stipule, terete, not swollen, not deflexed in age, sericeous, with antrorse, appressed, eglandular hairs 0.2-1.2 mm long; stipules 5.7-10.7 mm long, 1.9-3.6 mm wide, lanceolate (with a setaceous apex 1-2.5 mm long), sheathing, connate at the base, papery, brownish red, sericeous, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 1-flowered, grouped in 15-60-flowered cymes at the end of each brachyblast [ratio cymule length/leaf length = 1.4-2.1]; peduncles 3.8-8.6 mm long,  $\pm$  sericeous, with erect-patent to appressed, eglandular hairs 0.2-1 mm long; bracteoles 1.4-2.9 mm long, 0.4-1.5 mm wide, lanceolate, opposite, overlapping at base to appear sheathing. Flowers actinomorphic. **Sepals** (5.8)6.1-6.9(8.4) mm long, 2.2-3.7 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.3-1.1 mm long [ratio mucro length/sepal length = 0.06-0.18], sericeous, with antrorse, appressed, eglandular hairs 0.2-1.2 mm long on the abaxial surface, glabrous adaxially. **Petals** (8.5)9.1-11.1(13.9) mm long, 3.7-7.1 mm wide, erect-patent, rounded, without claw, usually white, sometimes pink, moderately hairy on the base of both adaxial and abaxial surface, with hairs 0.2-0.9 mm long. **Stamens** 10, both whorls bearing anthers; filaments 4.8-6.4 mm long, lanceolate with an abruptly narrowed apex, usually white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.7 mm long; anthers 0.7-1.3 mm long, yellow. Nectaries 5, hemispheric, dorsally woolly. **Gynoecium** 4.7-7.4 mm long, dark purple. **Fruit** 15.8-24.2 mm long, erect, discharge of seed-ejection type; mericarps 2.6-4.6 mm long, 1.4-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandu-

lar hairs 0.3-0.7 mm long; rostrum 9.6-16.9 mm long, with a narrowed apex 0.6-1.1 mm long, not twisted, sericeous, with antrorse, appressed eglandular hairs 0.1-0.6 mm long; stigmatic remnants 2.2-3.5 mm long, with 5 glabrous lobes. **Seeds** 2.3-2.9 mm long, 1.1-1.6 mm wide, reticulate-sinuous, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 579.

**Pollen.** *Geranium*-type (Bortenschlager 1967: 456).

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from May to October.

**Distribution.** This species is endemic to eastern of Maui Is., in Hawaii (Fig. 580).

**Habitat.** Montane grassland, forested gulches, rain-swept shrubby open forests, cinder cones, and fog-swept lava flows; 1580-2900 m.

**Discussion.** *Geranium multiflorum* is a shrub well characterized by the usually ovate leaves, which are serrate almost to the base, and by the many-flowered inflorescences with actinomorphic flowers. The leaves vary in shape and indument. Although most commonly the leaves are ovate, elliptic and obovate forms sometimes occur. The margin usually has 5-10 teeth on each side, from the apex to the petiole junction. In some cases the teeth are restricted to the apical third of the leaf, and forms with 3- or 4 apical teeth very rarely occur. In extreme cases nearly entire leaves and serrate leaves may occur on the same branch. The adaxial surface of the leaves is glabrous with lines of silky hairs on the nerves, but leaves with spreading hairs in the spaces between the nerves are also common. Exceptionally, some specimens have densely silky leaves adaxially. The abaxial surface of the leaves is consistently covered by a layer of flattened,

Fig. 580. Distribution of *Geranium multiflorum*.

appressed hairs and some spreading hairs on the nerves give a silky (rarely grayish) aspect to the abaxial surface. All this variability can be found intermingled in some populations, for instance in specimens from Koolau Gap (Degener 18012, 18241, 18421, 18422, 18423), suggesting that it does not deserve taxonomic recognition. Some of these forms with leaves silky on both surfaces and few teeth are reminiscent of *G. cuneatum* subsp. *tridens*, a taxon also present in this area. The ovate leaves and many-flowered inflorescences identify them, however, as *G. multiflorum*. The inflorescence structure of *G. multiflorum* is quite similar to that of *G. arboreum*, but more complex, with branches repeatedly trichotomous, and with many more flowers. As mentioned previously in *G. arboreum*, all nodes of the inflorescences have abscission lines. The bracteoles are opposite and not sheathing, but they overlap a base to give a sheathing appearance. The flowers of *G. multiflorum* are regular and the petals are white or with purple veins. Sometimes they have a purplish base, and exceptionally they can be purplish. *Geranium multiflorum* can be easily differentiated from *G. arboreum* by leaves not cordate at the base, by shorter, regular flowers, and by the shorter fruits lacking a long narrowed rostrum apex. Fosberg (1936: 4, 7-9) recognized two varieties of *G. multiflorum*: var. *multiflorum* from the island of Hawaii (with pilose leaves) and var. *canum* from Maui (with leaves densely silky or silvery abaxially). Fosberg (1936: 7) identified only two specimens as *G. multiflorum* var. *multiflorum*: the type and *Ussinger 692* (BISH). According to Wagner & al. (1990: 734) *Ussinger 692* (BISH) is *G. cuneatum* subsp. *cuneatum*, and the type was probably collected on Maui and incorrectly labeled as being from the island of Hawaii. Consequently, the presence of *G. multiflorum* on the island Hawaii remains to be confirmed. The type specimen (Brackenridge & al. s.n., US) has ovate leaves 34-44 mm long with 5-8 teeth

on each side, and spreading hairs on both surfaces, which is a bit deviant from the normal leaves found on plants from the island of Maui, which are glabrous adaxially (except for a few hairs on the nerves) and silky abaxially. Otherwise, the type matches the current concept of *G. multiflorum*. Thus, it would be rather premature to recognize infraspecific taxa in *G. multiflorum* as Carlquist & Bissing (1976) did. If new populations are found with leaves similar to the type, and if they have a distinct geographical range, it would be advisable to study this taxon further.

(lectotype, designated by Aedo 2017a: 175, BM-000797028!).

*Shrub*, 30-150 cm tall. *Rootstock* and roots unknown. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, glabrous. *Basal leaves* unknown, cauline leaves alternate; leaf laminae 1-3.6 cm long, 0.4-1.6 cm wide, not peltate, entire with dentate apex [with 3-7 teeth], obtriangular-cuneiform in outline, base cuneate,  $\pm$  coriaceous, with nerves not projected, glabrous (except on the nerves) to sericeous on both surfaces; segments 1; petioles up to 1.3 cm long, with an abscission zone between petiole and stipule, terete, not swollen, not deflexed in age, hairy to sericeous, with antrorse, appressed, eglandular hairs 0.1-0.7 mm long; stipules 3.1-12.2 mm long, 1.3-3.8 mm wide, lanceolate, sheath-

ing, connate at the base, papery, brownish red, hairy to sericeous, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, grouped in (3)7-12(25)-flowered cymes at the end of each brachyblast [ratio cymule length/leaf length = 1.3-3.6]; peduncles 2.8-12.5 mm long, hairy to  $\pm$  sericeous, with erect-patent to appressed, eglandular hairs 0.1-0.9 mm long; bracteoles 1.3-4.6 mm long, 0.7-1.6 mm wide, lanceolate, opposite, overlapping at base to appear sheathing. Flowers actinomorphic. *Sepals* 4.7-7.7(11.8) mm long, 1.6-3.8 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.2-0.8 mm long [ratio mucro length/sepal length = 0.03-0.12], hairy to  $\pm$  sericeous, with antrorse, appressed eglandular hairs 0.2-0.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (7)9.4-11.4(15.2) mm long, 2.2-7.5 mm wide, erect-patent, rounded, without claw, white, sometime with purple veins, glabrous to hairy on the base of both surfaces, with hairs 0.1-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.3-8.4 mm long, lanceolate, white, with scattered hairs 0.1-0.5 mm long on abaxial surface and margin; anthers 0.7-1.3 mm long, yellow. Nectaries 5, hemispheric, dorsally woolly. *Gynoecium* 4-7.8 mm long, purple. *Fruit* 14.4-32 mm long, erect, discharge of seed-ejection type; mericarps 2-4.9 mm long, 0.9-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, hairy to sericeous, with erect-patent, eglandular hairs 0.1-0.7 mm long; rostrum 9.8-20.1 mm long, with a narrowed apex 0.4-1.5 mm long, not twisted, hairy to sericeous, with antrorse, appressed eglandular hairs 0.1-0.6 mm long; stigmatic remnants 1.7-4.2 mm long, with 5 glabrous lobes. *Seeds* 1.6-3.2 mm long, 0.8-1.4 mm wide, reticulate-sinuous, uniformly colored, brown, glabrous. Cotyledons with entire margin.

*Pollen.* *Geranium*-type.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from January to October.

*Distribution.* This species is endemic to Hawaii (Hawaii Is. and Maui Is.).

*Habitat.* Shrubby slopes on volcanic rocks and open forests; 1500-3300 m.

*Discussion.* *Geranium cuneatum* is a shrub well characterized by the obtriangular-cuneiform leaves, which are dentate at the apex, and by many-flowered inflorescences with actinomorphic flowers. This species is similar in some aspects to *G. multiflorum*, although usually less robust. The most striking difference is in leaf shape, which is truncate and dentate at the apex in *G. cuneatum*, and ovate and serrate on most of the margin in *G. multiflorum*. In addition, *G. multiflorum* has longer and wider leaves. Some individuals with narrow leaves, sericeous on both surfaces, and few teeth (DeGENER 18241, 18423) would be intermediate forms between *G. multiflorum* and *G. cuneatum* subsp. *tridens*. However, their leaves with attenuate apices and 3 or 4 teeth on each side suggest that they should be identified as *G. multiflorum*. The stipules of *G. cuneatum* are sheathing and quite similar to those of *G. multiflorum*, although they lack the setaceous apex of *G. multiflorum*. The inflorescence of *G. cuneatum* is also quite similar to that of *G. multiflorum*, although with fewer flowers. In both species, the base of the peduncle and partial branchlets have abscission lines, and the bracteoles are also opposite and not sheathing.

*Geranium cuneatum* comprises variants that may be distinguished on the basis of leaf indument pattern and the number of leaf apical teeth. In *Geranium cuneatum* subsp. *tridens*, endemic to the island of Maui, the leaves are white-sericeous on both surfaces and usually have a tridentate apex. Some individuals have leaves with five apical teeth

mixed with those with tridentate leaves. The sepals and petals in subsp. *tridens* are longer than those in the remaining subspecies, although with some overlap. The petals of subsp. *tridens* usually have scattered hairs at the base of adaxial the surface, while they are usually glabrous in subsp. *cuneatum*. Among the four subspecies in the Hawaiian Islands, the one most most similar to subsp. *tridens* is subsp. *hololeucum*, since both have leaves that are white-sericeous on both surfaces. In subsp. *hololeucum*, however, the leaves mostly have 5-7 teeth at the apex. In rare cases some tridentate leaves occur on plants with mostly five dentate leaves. Subsp. *cuneatum* is characterized by leaves nearly glabrous except for a line of silky, appressed hairs on the nerves on both surfaces, only rarely with some scattered hairs between the nerves on some individuals. Subsp. *cuneatum* is similar to subsp. *hololeucum* in having 5-7 teeth (rarely only three) at the leaf apex. Finally, subsp. *hypoleucum* has the adaxial surface of the leaves almost glabrous except for a line of silky hairs on the nerves, and abaxially silky like subsp. *hololeucum*. The leaf apex of subsp. *hypoleucum* usually has 5-7 teeth, and with the same variability as that of subsp. *hololeucum* and subsp. *cuneatum*.

The four subspecies of *G. cuneatum* are weakly characterized, and only in the case of subsp. *tridens* clearly isolated geographically. The three subspecies present on the island of Hawaii appear to be partially allopatric. Subsp. *cuneatum* grows alone towards the west and subsp. *hypoleucum* is found mainly toward the south. Subsp. *hololeucum* grows only on the northeast-facing slopes of the volcano Mauna Kea. However, all three are found on the south and west slopes of Mauna Kea, and in the plateau between Mauna Kea and Mauna Loa. There is also an altitudinal trend, with subsp. *hololeucum* and subsp. *tridens* (both with the leaves silky on both surfaces) reaching high-

er altitudes, although with considerable overlap.

1. Leaves almost glabrous on both surfaces or sericeous on the abaxial surface.

2. Leaves usually glabrous except for a line of silky, appressed hairs on the nerves on both surfaces, rarely with sparse hairs between nerves.

#### 229a. subsp. *cuneatum*

2. Leaves sericeous on abaxial surface. 229c. subsp. *hypoleucum*

1. Leaves sericeous on both surfaces.

3. Leaves predominantly 5-7-toothed at apex.

#### 229b. subsp. *hololeucum*

3. Leaves predominantly tridentate at apex. 229d. subsp. *tridens*

Fig. 585. Distribution of *Geranium hanaense*.

both surfaces; segments 1; petioles up to 1.8 cm long, with an abscission zone between petiole and stipule, terete, not swollen, not deflexed in age, sericeous, with antrorse, appressed, eglandular hairs 0.2-0.7 mm long; stipules 4.9-9.8 mm long, 2.2-3.5 mm wide, lanceolate, sheathing, connate at the base, papery, brownish red, sericeous, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 1-flowered, grouped in 2-11(13)-flowered cymes at the end of each brachyblast [ratio cymule length/leaf length = 1.6-2.9]; peduncles (11)17.7-20.6(25.9) mm long,  $\pm$  sericeous, with erect-patent to appressed, eglandular hairs 0.5-1.1 mm long; bracteoles 2-4.3 mm long, 0.9-1.7 mm wide, lanceolate, opposite, overlapping at base to appear sheathing. Flowers actinomorphic. *Sepals* (6.8)7.2-8 mm long, 2.3-3.6 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.7-1.2 mm long [ratio mucro length/sepal length = 0.09-0.18], sericeous, with antrorse, appressed, eglandular hairs 0.3-0.6 mm long on the abaxial surface, glabrous adaxially. *Petals* 14.7-15.9 mm long, 5.6-8.6 mm wide, erect-patent, rounded, without claw, white, sometime with purple veins, hairy on the base of both surfaces, with hairs 0.4-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5-7.6 mm

long, lanceolate, with a purple apex, with scattered hairs 0.3-0.5 mm long on abaxial surface and margin; anthers 1.1-1.4 mm long, purple. *Nectaries* 5, hemispheric, dorsally woolly. *Gynoecium* 6.3-8.5 mm long, purple. *Fruit* 23-25 mm long, erect, discharge of seed-ejection type; mericarps 3.2-3.5 mm long, 1.4-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, hairy to sericeous, with erect-patent, eglandular hairs 0.4-1 mm long; rostrum 15.8-17.4 mm long, with a narrowed apex 1-1.7 mm long, not twisted, sericeous, with antrorse, appressed eglandular hairs 0.4-0.5 mm long; stigmatic remnants 2.3-3.1 mm long, with 5 glabrous lobes. *Seeds* 2.1-2.8 mm long, 1-1.2 mm wide, reticulate-sinuuous, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 584.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to October.

*Distribution*. This species is endemic to eastern of Maui Is., Hawaii (Fig. 585).

*Habitat*. Boggy areas in rainforests; 1650-1750 m.

*Additional specimens examined*. **USA**. HAWAII: Maui Is., Hana side, in bog closest to trail below Greensword Bog, 20°44'N, 156°6'W, 13 June 1982, *Funk* 206 (BISH); Maui Is., Hana Rain Forest, 20°44'N, 156°6'W, 13 June 1982, *Funk* 8A (BISH); Maui Is., Hana Rain Forest, near N rim of Kipahulu, 20°44'N, 156°6'W, 29 June 1973, *Harrison* 243 (BISH); Maui Is., Hanawi, above State Camp, esat fence, 20°44'N, 156°6'W, 5 Oct. 1997, *Wood* 6820 (BISH).

*Discussion*. *Geranium hanaense* is a dwarf, decumbent shrub that roots at the nodes. It is easy to distinguish by its leaves, which are obovate to elliptic, sericeous on both surfaces and mostly 5-7-toothed at the apex, and by its long partial inflorescences with long internodes and peduncles. The partial inflorescences of 2-6-flowered cymes in a complex structure are

quite similar to those of *G. arboreum*. *Geranium hanaense* might be mistaken at first for *G. cuneatum* subsp. *tridens* (both growing on Maui) or *G. cuneatum* subsp. *hololeucum* (from the island of Hawaii) because of the sericeous leaves. However, these taxa are erect shrubs not rooting at the nodes. According to Medeiros & St. John (1988: 218), plants of *G. hanaense*, raised at Haleakala National Park headquarters, retained their trailing decumbent branches, large flowers, and leaves with more than 3 teeth at the apex after four years in cultivation. In addition, *Geranium hanaense* generally has longer petioles, longer partial inflorescences (with longer internodes and peduncles), a longer sepal mucro, and longer petals than are found in either of the two *G. cuneatum* subspecies, although there is some overlap in all of these quantitative features. No original material of *Geranium hanaense* could be located for this study. The material seen, however, closely matches the protologue and was all collected from the vicinity of the type locality.

anthers; filaments 4.2-7.9 mm long, lanceolate, white, with scattered hairs 0.3-0.7 mm long on abaxial surface and margin; anthers 1.2-1.5 mm long, yellow. Nectaries 5, hemispheric, dorsally woolly. *Gynoecium* 4.3-8.7 mm long, purple. *Fruit* 19.1-26.9 mm long, erect, discharge of seed-ejection type; mericarps 2.9-3.5 mm long, 1.5-1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, hairy to sericeous, with erect-patent, eglandular hairs 0.4-0.5 mm long; rostrum 17.7-20.9 mm long, with a narrowed apex 2.3-2.9 mm long, not twisted, hairy to sericeous, with antrorse, appressed eglandular hairs 0.3-0.4 mm long; stigmatic remnants 2-2.3 mm long, with 5 glabrous lobes. *Seeds* 2.2-2.3 mm long, 1.2-1.4 mm wide, reticulate-sinuuous, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 586.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 433 [sub *G. humile*]).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from April to December.

*Distribution.* This species is endemic to northwestern of Maui Is., Hawaii (Fig. 587).

*Habitat.* Open foggy bogs, and *Metrosideros* Gaertn. montane wet shrublands; 1250-1850 m.

*Additional specimens examined.* **USA.** HAWAII: Maui Is., Hana side, in bog closest to trail below Greensword Bog, 20°44'N, 156°6'W, 13 June 1982, *Funk* 206 (BISH); Maui Is., Hana Rain Forest, 20°44'N, 156°6'W, 13 June 1982, *Funk* 8A (BISH); Maui Is., Hana Rain Forest, near N rim of Kipahulu, 20°44'N, 156°6'W, 29 June 1973, *Harrison* 243 (BISH); Maui Is., Hanawi, above State Camp, esat fence, 20°44'N, 156°6'W, 5 Oct. 1997, *Wood* 6820 (BISH).

*Discussion.* *Geranium hillebrandii* is a decumbent dwarf shrub that roots at the nodes. Its leaves are sericeous only on the abaxial surface, as is found in *G. cuneatum* subsp. *hypoleucum* and in *G. kauaiense*. The inflorescence of *G. hillebrandii* is quite similar to

that of *G. arboreum* and *G. hanaense* in having partial inflorescences of 2-6-flowered cymes in a complex structure. *Geranium hillebrandii* is easily recognized by the lines of sericeous hairs along the nerves of the adaxial surface of the leaves. Such lines are evident without magnification in *G. hillebrandii*, while they are only visible with a microscope in *G. cuneatum* subsp. *hypoleucum* and in *G. kauaiense*. *Geranium cuneatum* subsp. *hypoleucum* resembles *G. hillebrandii* in some features, among which it can be noted that it is an erect shrub with relatively narrow, apically truncate leaves. In *G. hillebrandii* the leaf apex is usually  $\pm$  attenuate, and most frequently with seven teeth. In addition, the stipules of *G. hillebrandii* are longer, the petiole shorter, and the inflorescence fewer flowered, the hairs of the petioles and peduncles are longer, as are the petals, the anthers and the narrowed apex of the rostrum. Most of these quantitative features show some overlap. The petals of *G. hillebrandii* are usually hairy at base on the adaxial surface and on the basal half of the abaxial surface, while those of *G. cuneatum* subsp. *hypoleucum* have only scattered hairs at the base on the adaxial surface (rarely glabrous). *Geranium kauaiense* is close to *G. hillebrandii*. Both are dwarf, decumbent shrubs that root at the nodes and grow in bogs. The first may be distinguished by its narrower leaves, truncate and 5-toothed apex, shorter stipules and longer petiole. Partial inflorescences of *G. kauaiense* are significantly longer because of longer internodes and peduncles. In both species, however, the flowers are fewer, which is a useful feature for separating these species from *G. cuneatum* subsp. *hypoleucum*. Additionally, the sepals, petals, anthers and narrowed apex of the rostrum are shorter in *G. kauaiense* than in *G. hillebrandii*, and the stigmatic remnants are longer. Most of these quantitative features show some overlap. Hillebrand (1888) described *G. humile* (here *G. hillebrandii*) including plants

from Maui and Kaua'i. Rock (1911: 9) segregated the plants from Kaua'i as a different variety, which was also recognized by Fosberg (1936: 18). St. John (1984: 481) subsequently recognized the plants from Kaua'i as *G. kauaiense*. Consequently, *G. humile* should be typified by the Maui specimen cited by Hillebrand and *G. kauaiense* on those from Kaua'i cited by Rock (1911: 9).

**Discussion.** *Geranium kauaiense* is a decumbent dwarf shrub that roots at the nodes. It is easy to distinguish by its narrow leaves that are five-toothed across the truncate apex and have a nearly glabrous adaxial surface and sericeous abaxial surface, and by its long partial inflorescences with long internodes and peduncles and few flowers. The inflorescence of *G. kauaiense* is quite similar to that of *G. hillebrandii* with partial inflorescences of 2-6-flowered cymes in a complex structure. *Geranium kauaiense* appears to be close to *G. hillebrandii* and in some aspects is similar to *G. cuneatum*

subsp. *hypoleucum* (see discussion under *G. hillebrandii*). Sinclair (1885, tab. 35) illustrated *G. kauaiense* under the name *G. cuneatum*. Rock (1911: 9) and Knuth (1912: 216) recorded the name as "*Geranium cuneatum* var. *Sinclair*" in synonymy under *G. humile* var. *kauaiense* and *G. humile*, respectively. It seems, however, that no epithet was ever proposed by either of these authors. The type collection of *Geranium humile* var. *kauaiense* has been somewhat confusing. Rock (1911: 9), in describing *G. humile* var. *kauaiense*, stated: "Kauai: Summit of Waialeale, elevation 5000 feet, on moss-covered rocks (Rock n. 4931, flowering Sept. 24, 1909, Oct. 20, 1911)". I have examined a collection by Rock numbered 4926 (BISH). This specimen is considered to be, in a handwritten note on the sheet, "part of Rock 4931 collection". Fosberg (1936: 19) stated "September 24, 1909, J. F. Rock 4931 (type) and 4926 (probably same collection)." At NY is another collection by Rock with the same locality and date, but unnumbered, which also seems to be original material.

**II.d Geranium sect. Incana** Reiche in Engl. & Prantl, Nat. Pflanzefam. 3(4): 8. 1890. TYPE: *Geranium incanum* Burm. f. (art. 10.8).

Leaves and petiole without any abscission zone. Stipules (2)3-5(11)-fid, with linear to lanceolate and deep lobes. Mericaps with a basal callus.

Oldenland s.n.* (lectotype, first-step, designated by Kok-

waro 1971: 134, G-PREL, here in second-step, see discussion).

**Perennial herbs**, 14-80 cm tall. **Rootstock** 2.7-9.8 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** procumbent to ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, usually appressed, eglandular hairs 0.3-0.9 mm long and, rarely, patent, glandular hairs 0.5-0.6 mm long. **Basal leaves** usually not present, cauline leaves alternate and upper opposite; leaf laminas (1)2.5-3.8(7.8) cm long, 1.3-9.7 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs, rarely glabrous, on the adaxial surface and sericeous abaxially; segments 5, in 1 plane, middle segment rhombic (with narrow linear lobes 0.5-2.3(2.7) mm wide), (0.4)0.6-0.8(1.4) mm wide at the base [ratio segment width at the base/middle segment length = (0.02)0.03-0.05(0.07)], 5-34(47)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.27)0.43-0.56(0.60)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, usually appressed, eglandular hairs 0.2-0.6 mm long; stipules 3.2-12 mm long, 1-8 mm wide, 2-5-fid, with linear lobes 2.2-9.7 mm deep, 0.2-1 mm wide, free, papery, brown, with eglandular hairs on abaxial surface, ± glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.5)2.4-3.9(6.8)]; peduncles (18)30-77(133) mm long, with retrorse, ± appressed, eglandular hairs 0.2-0.7 mm long and, sometimes, patent, glandular hairs 0.3-0.7 mm long; bracteoles 1.8-8.2 mm long, 0.2-1.3 mm wide, linear-lanceolate, whorled; pedicels (7.9)18.7-32.5(44.1) mm long, with retrorse, ± appressed, eglandular hairs 0.1-0.7 mm long and, sometimes, patent, glandular hairs 0.2-0.7 mm long. Flowers actinomorphic.

*Sepals* (4.2)6.1-7.4(8.3) mm long, 1.6-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.4)0.8-1.3(1.6) mm long [ratio mucro length/ sepal length = (0.07)0.12-0.19(0.24)], sericeous, with appressed, eglandular hairs 0.1-0.8 mm long and, sometimes, patent, glandular hairs 0.2-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (5.2)8.5-13.6(17.5) mm long, (3.1)4.9-9.6(13.3) mm wide, erect-patent, rounded or emarginate (notch 0.4-2.2 mm deep), without claw, white, pink or purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.2-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments (2)4.3-6.1(8.5) mm long, lanceolate, yellow, with scattered eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers (1)1.3-1.9(2.3) mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 2.1-7.6 mm long, yellow to pink. *Fruit* (11.1)18-28(35) mm long, erect, discharge of seed-ejection type; mericarps 2.6-4.6 mm long, 1.4-2.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.4-0.9 mm long and, sometimes, patent, glandular hairs 0.4-0.8 mm long; rostrum 10-26.6 mm long, with a narrowed apex 0.4-4.4 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.8 mm long and, sometimes, patent, glandular hairs 0.4-0.8 mm long; stigmatic remnants 0.8-5.7 mm long, with 5 glabrous lobes. *Seeds* 1.7-2.9 mm long, 1.1-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 431; Verhoeven & Venter 1992: 441, 442).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from January to December.

*Distribution.* This species ranges from southern Tanzania to south-

western South Africa and it is introduced in Australia and U.S.A.

*Habitat.* Coastal dunes, disturbed areas, grassland and forest edges; 0-3200 m.

*Discussion.* The group, comprising *G. incanum* and related species (*G. magniflorum*, *G. nyassense*, *G. multisectum* and *G. vagans*), is characterized by their palmatisect leaves with narrow lobes. It is the most complex group of the sect. *Incana*. Essentially, the entities proposed by Hilliard & Burt (1985) have been accepted with some modification. The variability of the characters of these entities that is related to their range makes it advisable to group them, at least partially, as Laundon (1961, 1963) did. For this reason *G. magniflorum* and *G. nyassense* have been subordinated to *G. incanum* as subspecies. Although to a lesser extent *G. multisectum* and *G. vagans* are sometimes also difficult to separate from *G. incanum* s.l. The result is an unsatisfactory taxonomy, similar to that which occurs in those groups that are still in the process of speciation. An analysis of the variation of the populations in the field would probably help to better understand the variability of these taxa and, if necessary, to propose a more operative delimitation.

The typification proposed by Kokwaro (1971) for *G. incanum* needs some clarification, because he only stated: "Type: South Africa, Cape of Good Hope, *Oldenland* (Herb. Oldenland, G, holo.)". The most important part of Oldenland's herbarium came into the hands of the Burman family and is now in G, into the prelinnean collection, sometimes called the Burman collection (G-PREL). In Burman's herbarium there are seven sheets that could be related to this species, but only four of them fit the current concept of *G. incanum*. One of the latter shows a 2-flowered cymule with two additional flowers at the base, very similar to the one that appears in the drawing of the protologue. The label of this sheet reads "*Geranium*

*incanum* foliis tenuissimis multifidis quinquepartitis, laciniis linearibus pedunculis subbifloris", and it is written in Burman's hand according to N. Fumeaux (*in litt.*). Burman attributes this polynomial to Oldenland in the protologue (part underlined). Consequently this specimen is here designated as lectotype in second step.

1. Leaves with linear-lanceolate, plane lobes; pedicels and sepals usually with glandular hairs

**233c. subsp. nyassense**

1. Leaves with narrow, linear, revolute lobes; pedicels and sepals with or without glandular hairs

2. Lower leaves lacking or distributed along the stem; pedicels and sepals without glandular hairs; sepal mucro (0.7)1-1.5(1.6) mm long

**233a. subsp. incanum**

2. Lower leaves in a ± persistent rosette; pedicels and sepals usually with glandular hairs; sepal mucro (0.4)0.7-0.9(1.4) mm long

**233b. subsp. magniflorum**

**233a. *Geranium incanum* Burm. f. subsp. incanum**

*Geranium multifidum* Sweet, Geraniaceae 3, tab. 245. 1825, nom. illeg., non Andrews, 1805. *Geranium incanum* var. *multifidum* Sweet ex Hillard & B.L. Burt, Notes Roy. Bot. Gard. Edinburgh 42(2): 197. 1985. TYPE LOCALITY: "We first observed this curious species of *Geranium*, in the summer of 1819, in the garden of Mr. Burchell, at Fulham; where we saw several plants of it in bloom. It is a native of the Cape of Good Hope, and was raised from seed, brought from that country, by Mr. W.J. Burchell; and from a plant given by him to Robert Henry Jenkinson, Esq. our drawing and description were taken last summer". TYPE: Sweet, Geraniaceae 3, tab. 245, 1825 (lectotype, designated by Hilliard & Burt 1985: 197).

*Stem* procumbent, with retrorse, usually appressed, eglandular hairs 0.3-0.9 mm long. *Basal leaves* not present (no rosette); middle leaf segment rhombic (with narrow linear lobes 0.7-0.8(1.5) mm wide), (0.4)0.6-

0.7(0.9) mm wide at the base. *Peduncles* (28)30-97(133) mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.7 mm long; pedicels (7.9)16.7-35.6(44.1) mm long, with retrorse,  $\pm$  appressed, eglandular hairs 0.3-0.7 mm long. *Sepals* (4.6)6.5-7.6(8.2) mm long, 2.2-3.4 mm wide, with mucro (0.7)1-1.5(1.6) mm long, sericeous, with appressed, eglandular hairs 0.2-

0.4 mm long on the abaxial surface. *Petals* (5.6)10-15.6(17.5) mm long, (3.2)5.4-11(13.3) mm wide, rounded or emarginate (notch 0.5-2.2 mm deep), white to pink. Fig. 590.

*Pollen*. *Geranium*-type (Verhoeven & Venter 1992: 441, 442).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This subspecies ranges through Western Cape and Eastern Cape, in South Africa and it is introduced in Australia and U.S.A. (Fig. 591).

*Habitat*. Coastal dunes, disturbed areas, grassland, among scrub, or in open places on forested mountain slopes; 0-1500 m.

*Representative specimens examined*.

**Discussion.** *Geranium incanum* subsp. *incanum* is a procumbent herb with a thin vertical rootstock branch-

ing from the base into multiple aerial stems, and with thin roots. The lower leaves are generally arranged along the stem base. Sometimes at the base of the branches they are very close together but do not form basal rosettes. The leaves are palmatisect with five segments divided in linear and revolute lobes which vary from entire to pinnate, and are arranged in a single plane. They are covered by ± scattered, appressed, eglandular hairs on the adaxial surface and are sericeous, with appressed, eglandular hairs, abaxially. On the stem, the inflorescence and other parts of the plant the indumentum is also eglandular. The sepals are sericeous, with antrorse, appressed hairs. The petals are long although they vary in size and color and are usually emarginate.

According to Hilliard & Burt (1985: 197) the var. *multifidum* is distinguished from the var. *incanum* by its pink and larger petals. The length of the petals shows a considerable overlap and the color also seems highly variable, which discourages the taxonomic recognition of these entities.

**233b. *Geranium incanum* subsp. *magniflorum* (R. Knuth) Aedo, comb. nov.** *Geranium magniflorum* R. Knuth, Bot. Jahrb. Syst. 40: 68. 1908. TYPE LOCALITY: "Natal: Drakenberg, 2700-3000 m, an grasigen Stellen (Thode n. 13! -- Blühend im Februar). -- Typus in herb. Berol.". TYPE: South Africa. Cobham Forest reserve, Lakes cave area, 29°40'S, 29°20'E, 15 Dec. 1987, *Manning & al.* 16065 (NU).

**Discussion.** *Geranium incanum* subsp. *magniflorum* differs from subsp. *incanum* in its somewhat thicker rhizome and its ascending habit. The basal leaves of subsp. *magniflorum* remain grouped at the base of the stem forming a rosette-like which gives it a very characteristic appearance. The leaf is very similar to that of the subsp. *incanum*, palmatisect, with very narrow, revolute, linear lobes and discolorous. Leaf lobes are most often entire but can also be pinnate. The subsp. *magniflorum* frequently has glandular hairs on the inflores-

cence while subsp. *incanum* is always eglandular. The sepal mucro of subsp. *magniflorum* is somewhat shorter than that of subsp. *incanum* but with some overlap.

In *Hilliard & Burt* 18000 (K, PRE) collection, the basal leaves are almost palmatisect, while the stem leaves are like those of other more typical specimens of subsp. *magniflorum*; otherwise, it fits very well with the current concept of subsp. *magniflorum*. The specimen *Bolus* 148 (K) lacks the basal part of the plant and shows leaves which are not clearly sericeous abaxially but, in accordance with *Hilliard & Burt* (1985: 195), it is provisionally included here under subsp. *magniflorum*.

Fig. 592. *Geranium incanum* subsp. *magniflorum*. a. Fragment of the habit. b. Leaf. (Based on: *Wright* 2012, NU).

Because the holotype *G. magniflorum* is no longer extant, a neotype is designated. The neotype here chosen matches the original description, and was collected in the same region as indicated in the protologue.

**Discussion.** *Geranium incanum* subsp. *nyassense* differs from subsp. *incanum* in its leaf shape and its indumentum. The leaf is very similar to that of the subsp. *incanum*, being palmatisect, and discolorous, but their leaf lobes are usually linear-lanceolate, not revolute and not as narrow as in subsp. *incanum*. However, scattered throughout the *nyassense* area there are specimens with very narrow and revolute lobes [e.g.: *Gereau & Kayombo 4082* (UPS), *Polhill & Paulo 1500* (B), *Richards 7563*, *7706* (B), *Semsei 1658* (B), *Soltz 2599* (NY), *Slotz 2060* (B, C, G, PR)] or, sometimes, with a part of the leaves of linear-lanceolate and not revolute lobes. These samples are difficult to separate from subsp. *incanum*, which reinforces the hypothesis that they are not independent species in spite of the geographical separation. The subsp. *nyassense* frequently has glandular hairs on the inflorescence while subsp. *incanum* is always eglandular. The petals of subsp. *nyassense* are somewhat shorter than those of subsp. *incanum* but with some overlap, and frequently, not emarginate.

*Geranium incanum* subsp. *nyassense* shares with subsp. *magniflorum* the indumentum of the inflorescence, frequently glandular, but differs from it in the leaf shape and in the arrangement of lower leaves. In subsp. *magniflorum* the leaf lobes are similar to subsp. *incanum*, but the lower leaves remain grouped at the base of the stem forming a rosette-like. The subsp. *magniflorum* has petals somewhat longer than in subsp. *nyassense*, and more often emarginate.

The type label of *G. ukingense* shows some inconsistency with the protologue, especially in the locality. The label reads "*Geranium ukingense* Knuth / Nr. 2060 / Nyassa Hochland – Station Kyimbila / Seehöhe 16-1800 Meter / 1912 / leg. A. Stolz" [the handwritten part of the label has been underlined]. I have assumed that the handwritten part is the correct and that the typewritten part was from a previous label that was reused. The specimens *Stolz 1389*, *2060* (B) are from the herbarium of Rudolf Gross, acquired in 1946, after Berlin herbarium fire that destroyed the corresponding holotypes. In both *G. nyassense* and *G. ukingense* a lectotype has been chosen among the available isotypes, in accordance with art. 9.12 of the Shenzhen Code.

*Perennial herbs*, 13-45 cm tall. *Rootstock* 2-6 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* procumbent to ascending, leafy, rarely rooting on nodes, stolons absent, without vegetative stems, with retrorse, usually appressed, eglandular hairs 0.2-0.6 mm long. *Basal leaves* sometimes in a  $\pm$  persistent rosette, cauline leaves alternate and upper opposite; leaf laminae (0.9)1.5-2.2(2.9) cm long, 0.9-3.3 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on the adaxial surface and sericeous (rarely also with patent, glandular hairs) abaxially; segments 5, in more than 1 plane, middle segment rhombic (with narrow linear lobes (0.3)0.4-0.7(0.8) mm wide), 0.3-0.5(0.6) mm wide at the base [ratio segment width at the base/middle segment length = (0.02)0.03-0.04(0.05)], 33-65-lobed in distal half [ratio secondary sinus length/middle segment length = (0.34)0.38-0.51(0.59)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with usually retrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules 3.5-7.9 mm long, 1.4-5.8 mm wide, 2-4(5)-fid, with linear lobes 2.2-5.6 mm deep, 0.2-1 mm wide, free, papery, brown, with eglandular hairs on abaxial surface,  $\pm$  glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.5-8.8]; peduncles (23)34-63(92) mm long, with patent to retrorse, uncinete, eglandular hairs 0.2-0.7 mm long and, usually, patent, glandular hairs 0.3-0.7 mm long; bracteoles 3.8-6.1 mm long, 0.6-1.6 mm wide, linear-lanceolate, whorled; pedicels

(15)23-36(38) mm long, with patent to retrorse, uncinete, eglandular hairs 0.2-0.4 mm long and, usually, patent, glandular hairs 0.3-0.8 mm long. Flowers actinomorphic. *Sepals* (5.8)6.4-7.6(7.8) mm long, 1.8-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.2)0.4-0.6(0.9) mm long [ratio mucro length/sepal length = (0.04)0.06-0.10(0.13)], sericeous, with  $\pm$  appressed, eglandular hairs 0.2-0.4 mm long and, usually, patent, glandular hairs 0.3-0.8 mm long on the abaxial surface, glabrous adaxially. *Petals* (10.7)12.2-14.8(16.6) mm long, (6)7.5-10.6(15.9) mm wide, erect-patent, emarginate (notch 0.6-1.7 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments (3.2)3.9-5(6.1) mm long, lanceolate, pink, with scattered eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 1.4-1.8 mm long, purple. *Nectaries* 5, hemispheric, usually with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 4.5-7.7 mm long, purple. *Fruit* (22)23-26(28.9) mm long, erect, discharge of seed-ejection type; mericarps 3.4-4 mm long, 1.7-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.8 mm long and usually, patent, glandular hairs 0.7-0.8 mm long; rostrum 14-20 mm long, with a narrowed apex 1.2-4.3 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.2-0.4 mm long and usually, patent, glandular hairs 0.4-0.8 mm long; stigmatic remnants 2.4-4.2 mm long, with 5 glabrous lobes. *Seeds* 2.2-2.7 mm long, 1.5-2 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 594, 595.

*Pollen*. *Geranium*-type (Verhoeven & Marais 1990: 167; Verhoeven & Venter 1992: 445).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from October to July.

*Distribution*. This species ranges from Eastern Cape, through Lesotho, KwaZulu-Natal and Free State to Gauteng and Mpumalanga, in South Africa (Fig. 596).

*Habitat*. Grassland, marshy places and along streamlines; 1250-3100 m.

*Representative specimens examined.*

Discussion. *Geranium multisectum* is a procumbent to ascending herb with a thin vertical rootstock branching from the base into multiple aerial stems, and with thin roots. According to Hilliard & Burtt (1985: 191) stems sometimes root when in contact with the ground which has been verified in some herbarium specimens. Hilliard & Burtt (1985: 191) indicated that basal leaves are tufted like in *G. incanum* subsp. *magniflorum*. However, in the specimens studied only occasionally are leaves gathered in a basal rosette. The palmatisect leaves of *G. multisectum* have segments divided in short, narrow and revolute lobes that are pinnate. *Geranium multisectum* is quite similar to *G. incanum*, with which it has sometimes been confused. In *G. incanum* the leaves are arranged in a single plane while in *G. multisectum* the lateral lobes of the middle seg-

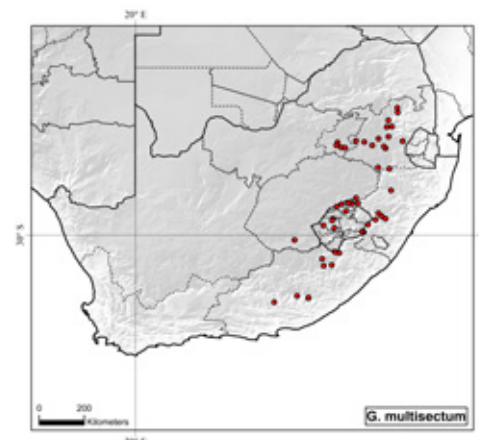

Fig. 596. Distribution of *Geranium multisectum*.

ment are pinnate and  $\pm$  perpendicular to the plane formed by the segments, which gives the leaf a much entangled appearance when it dries. The leaves of *G. multisectum* are covered by  $\pm$  scattered, appressed, eglandular hairs on the adaxial surface and are sericeous, with appressed, eglandular hairs, abaxially. Occasionally, glandular, patent hairs are found on both surfaces. The indumentum of stem, petioles and inflorescence usually comprises retrorse, eglandular hairs. On the inflorescence the presence of patent, glandular hairs is also frequent. The sepals are sericeous and usually have glandular hairs. The sepal mucro is very short. The petals are long and usually emarginate.

Some specimens of *G. multisectum* from Mpumalanga (northern South Africa) have leaves with narrow lobes that are not sericeous abaxially [e.g.: Codd & de Winter 3359 (PRE), Edwards 3403 (NU), Hutchinson 2731 (K), Leistner 523 (K, UPS), Pott s.n. (PRE-662446)]. In some this sericeous indumentum could have been lost, since there are areas covered with more or less scattered appressed hairs. In others the appressed hairs are reduced to the nerves. However, these specimens have the lateral lobes of the middle segment,  $\pm$  perpendicular to the plane formed by the segments and longer petals, which distinguishes them easily from *G. vagans*.

**Discussion.** *Geranium vagans* is an ascending herb that climbs on the surrounding vegetation. It has a vertical rootstock branching from the base into multiple aerial stems, with thickened roots. The leaves are palmatisect, with lobes that vary in shape and width. In some herbarium specimens the lobes are long, linear and with revolute margins. In other specimens the lobes are linear-lanceolate, somewhat wider, and not revolute. In *Schlieben 3486* (M) outer basal leaves with wider lobes and the inner basal and the cauline leaves with narrower and more linear lobes can be seen, suggesting that this variability lacks taxonomic importance.

The indumentum of *G. vagans* includes eglandular and glandular hairs, although in some specimens the latter are partially or totally missing. Laundon (1963: 135) recognizes the subsp. *whytei* (from Mt. Zomba, Malawi) for its fruit which lacks glandular hairs. In this study, specimens with abundant glandular hairs on the fruit have been found in this area, along with others with few or none, which does not support Laundon's proposal. The leaves of *G. vagans* have appressed, eglandular hairs all

over the adaxial surface and usually restricted to the veins and margins on the abaxial surface. Occasionally, eglandular hairs are also found between the nerves on the abaxial surface and glandular hairs on both surfaces.

In an initial observation, some specimens of *G. caffrum* are quite similar to *G. vagans* in leaf shape. However, in *G. caffrum* the base of the middle segment is wider and the width of the lobes is also greater, although some overlap. Furthermore, the indumentum of *G. caffrum* rarely includes glandular hairs. Both species are allopatric and are separated by about 1000 km.

Some specimens of *G. multisectum* from Mpumalanga (northern South Africa) are similar to *G. vagans* by their narrow lobes non-sericeous abaxially. However, these specimens have the lateral lobes of the middle segment,  $\pm$  perpendicular to the plane formed by the segments and much longer petals than *G. vagans*.

---

*Discussion.* *Geranium pulchrum* is a subshrub with a strong and  $\pm$  vertical rootstock. Its stem is ligneous towards the base and can reach 12 mm in diameter. The main stem has usually about 1 m tall, but the herbaceous branches spread over other plants and reach up to 3 m in length. Basal leaves are absent, but on the tip of the branches some leaves are grouped in a rosette-like structure. Along the branches the leaves are alternately arranged, while towards the inflorescence they are shorter and opposite.

*Geranium pulchrum* shares with *G. brycei* its general aspect, and deeply palmatifid and discolor leaves. The inflorescence is also quite similar, with peduncles opposite to the upper leaves along the branches, but in well grown specimens, forming large compound cymes, lacking leaves on the upper nodes and with ultimate peduncles mostly 2-flowered. The indumentum comprises both glandular and eglandular hairs on the inflorescence, and only appressed eglandular hairs on petioles and stem. In contrast, *G. pulchrum* is a more robust plant, that has leaves a bit less divided with the sericeous indumentum of the abaxial surface covering the nerves, longer anthers, fruits with longer stigmatic remnants, and rostrum with longer narrowed apex.

According to Hilliard & Burt (1985: 183) *G. robustum* has a more restricted and allopatric distribution in relation to *G. brycei*.

**237. *Geranium brycei* N.E. Br., Bull. Misc. Inform. 1901(175/177): 120. 1901. TYPE LOCALITY:** "South Africa. Basutoland, on Machacha Mountain, in a moistkloof, alt. 9500 ft., Right Hon. J. *Discussion.* Among herbarium sheets of *G. brycei* only fragments without underground parts are available. However, Hilliard & Burt (1985: 183), who collected this species many times, stated that is a "... perennial herb or subshrub up to 1 m tall, though often much shorter, stems one or several from the base, eventually bare and woody there, up to c. 10 mm diam., erect or decumbent...". The basal leaves are unknown as well, but on the tip of the branches some leaves are grouped in a rosette-like structure, as in *G. pulchrum*. Along of the branches the leaves are alternately arranged, while towards the inflorescence they are shorter and opposite.

*Geranium brycei* is easily recognized by its deeply palmatifid and

discolor leaves. The sericeous indumentum of the abaxially surface is distinctive because it is dense except on the nerves, which are clothed with long spreading hairs. In fact, the nerves are visible, but the surface between nerves is completely covered by a tangle of white hairs.

The peduncles are opposite to the upper leaves along the branches. However well grown specimens form large compound cymes, lacking leaves on the upper nodes and with ultimate peduncles mostly 2-flowered. The inflorescence usually has an indumentum of both glandular and eglandular hairs, although in some specimens glandular hairs are scarce.

*Geranium brycei* is close to *G. pulchrum*. The latter has petioles with appressed hairs and leaves uniformly sericeous on the abaxial side and acute and less deeply divided segments.

**Discussion.** *Geranium robustum* is a subshrub with a strong and  $\pm$  vertical rootstock and a woody stem with multiple ligneous branches from the base. The plant can reach about 1 m in height. The basal leaves are unknown, but the lack of rosette should be confirmed in young plants. The ligneous part of the branches is naked

and ends in an herbaceous part with alternate leaves which are replaced by opposite leaves towards the apex.

*Geranium robustum* shares with *G. pulchrum* and *G. brycei* their general aspect, discoloured leaves, long and emarginate petals and long fruits, but differs from both by its palmatisect leaves. The inflorescence is also quite similar, with peduncles opposite to the upper leaves along the branches. However in well grown specimens forming large compound cymes, leaves are lacking on the upper nodes and ultimate peduncles are mostly 2-flowered. The indumentum comprises both glandular and eglandular hairs on the inflorescence, and only appressed, eglandular hairs on petioles and stem.

**239. *Geranium discolor*** Hilliard & B.L. Burt, Notes Roy. Bot. Gard. Edinburgh 42(2): 186, 173 fig. 1 F. 1985. TYPE LOCALITY: "E Cape, Stutterheim distr., 3227 CB, Kabusie Forest, 20 x 1980, Hilliard & Burt 13194 (NU holo., E iso.)". TYPE: South Africa. *Perennial herbs*, 22-60 cm tall. *Rootstock* and roots unknown. *Stem* procumbent to ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with  $\pm$  patent, eglandular hairs 0.4-1 mm long. *Basal leaves* not present (no rosette), cauline leaves alternate and upper opposite; leaf laminae (2.1)2.8-3.1(3.2) cm long, 2.2-3.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.54)0.62-0.68(0.76)], polygonal in outline, base cordate,  $\pm$  coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs on the adaxial surface (sometimes nearly glabrous), sericeous abaxially;

segments 5, in 1 plane, middle segment obtriangular, (4.4)6.5-7.9(9.9) mm wide at the base [ratio segment width at the base/middle segment length = (0.34)0.37-0.43(0.47)], 5-7-lobed in distal half [ratio secondary sinus length/middle segment length = (0.14)0.19-0.25(0.28)]; petioles up to 18 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1 mm long; stipules (7.7)8.4-10.9(13.6) mm long, 1.2-5.5 mm wide, (2)3-fid, with linear lobes 3.8-9.7 mm deep, 0.3-0.9 mm wide, free, papery, brown, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (2.1)3.2-5.1(6)]; peduncles (50)69-81(130) mm long, with patent to retrorse,  $\pm$  appressed, eglandular hairs 0.2-1.1 mm long; bracteoles 7.3-10.9 mm long, 0.8-1.9 mm wide, linear-lanceolate, whorled; pedicels (17)26-46(58) mm long, with patent to retrorse,  $\pm$  appressed, eglandular hairs 0.3-1.2 mm long. *Flowers* actinomorphic. *Sepals* (7.6)8.4-9.8(10.9) mm long, 2.9-4.4 mm wide, lanceolate, smooth, not accrescent, nerves 5(7), mucro (1.1)2-2.3(2.8) mm long [ratio mucro length/sepal length = (0.13)0.22-0.29], sericeous, with  $\pm$  appressed, eglandular hairs 0.2-1.4 mm long and, rarely, patent, glandular hairs 0.5-0.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (13.2)17.1-19.6(20.7) mm long, (9.7)10.2-12.8 mm wide, erect-patent, slightly emarginate (notch 0.6-1.3 mm deep), without claw, pale to dark purple, white towards the base, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.6-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments (7.5)8.8-10.4(10.7) mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.4 mm long; anthers 2-2.7 mm long, yellow. *Nectaries* 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 8.6-11

mm long, purple. *Fruit* 28.5-31.9 mm long, erect, discharge of seed-ejection type; mericarps 4.3-5.1 mm long, 1.7-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 1.1-1.9 mm long; rostrum 18.2-

20.9 mm long, with a narrowed apex 3.8-5.1 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.4-1.2 mm long; stigmatic remnants 4.3-5.5 mm long, with 5 glabrous lobes. *Seeds* 3.3-3.4 mm long, 1.5-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 607.

*Pollen.* *Geranium*-type (Verhoeff & Marais 1990: 166; Verhoeff & Venter 1992: 441).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from October to January.

*Distribution.* This species is endemic to central Eastern Cape, in South Africa (Fig. 608).

*Habitat.* Moist places on forest edges, and among rocks on open mountain slopes; 1200-1800 m.

*Additional specimens examined. South Africa.* EASTERN CAPE: Amatole Mountains, near Cata, 32°33'S, 27°7'E, 11 Feb. 1983, *Furness & Phillipson* 228 (MO); Amatole Mountains, below Gaikas Kop, 32°33'S, 26°56'E, 3 Dec. 1982, *Furness & Phillipson* 54 (PRE); Amatole Mountains, below Gaikas Kop, 32°33'S, 26°56'E, 3 Dec. 1982, *Phillipson* 54 (MO); Amatole Mountains, below Gaikas Kop, 32°33'S, 26°56'E, 17 Dec. 1984, *Phillipson* 976 (K, MO, PRE, UPS); Stutterheim district, Thomas Mountain, 32°34'S, 27°14'E, 9 Dec. 1981, *Hilliard & Burtt* 14787 (K, M, MO); Hogsback Forest Reserve, Fort Beaufort, 60 mi NNE Grahamstown, 32°35'S, 26°56'E, 25 Nov. 1969, *Dahlstrand* 1843 (GB); Hogsback F.R. above Kettespont Falls, 32°35'S, 27°1'E, 9 Dec. 1977, *Hilliard & Burtt* 10950 (MO, NU); Stutterheim district, Mt Kemp, near radio mast, 32°40'S, 27°15'E, 14 Dec. 1977, *Hilliard & Burtt* 11047 (B, NU, PRE); King Williams Town Division, Mt Kemp, 32°40'S, 27°15'E, 13 Jan. 1947, *Leighton* 2740 (BOL); at foot of Pirie, 32°43'S, 27°16'E, 1893, *Flanagan* 2161 (MO, PRE).

*Discussion.* *Geranium discolor* is a perennial herb prostrate to ascend-

Fig. 608. Distribution of *Geranium discolor*.

ing. The stem is branched from the base, somewhat lignified in the lower part and naked or with the remains of stipules, apparently without rosette. Nevertheless, the lack of rosette should be confirmed in young plants. Its underground parts are not well known owing to the scarce amount of herbarium material available. The indumentum is predominantly eglandular but, according to Hilliard & Burt (1985: 187), some specimens can have glandular hairs on peduncles or sepals. *Geranium discolor* is easily recognized by its subcoriaceous leaves, not deeply palmatifid and sericeous on the abaxial surface, and its long and wide petals shallowly notched. Its stipules are usually trifid with narrow and deep lobes. Sometimes bifid stipules appear in some nodes.

Hilliard & Burt (1985: 187) reported a possible hybrid between *G. discolor* and *G. amatolicum*, collected among the parents (Hilliard & Burt 14796a, E, NU). *Geranium discolor* has sometimes been confused with *G. ornithopodon*, from which it is easily separated by its less deeply divided leaves and sericeous abaxially.

**240. *Geranium harveyi*** Briq., *Annuaire Conserv. Jard. Bot. Genève* 11/12: 183. 1908. *Geranium sericeum* Harv. in Harv. & Sond., *Fl. **Discussion.** *Geranium harveyi* is a perennial herb with a spreading stem suberect to ascending. The stem is branched from the base, somewhat lignified in the lower part and naked or with the remains of stipules, apparently without rosette. Nevertheless, the lack of rosette should be confirmed in young plants. Its underground parts are poorly known owing to the scarce availability herbarium material, but in some specimens a thin vertical rootstock appears. *Geranium harveyi* is easily recognized by its leaves, which are deeply palmatifid and sericeous on both surfaces. The indumentum of the adaxial surface is dense and white on young leaves, but in some herbarium specimens mature leaves show a less dense and grey indumentum. Its stipules are usually trifid with narrow and deep lobes but, sometimes bifid or 4-fid stipules appear in some nodes. *Geranium harveyi* is sometimes confused with *G. canescens*. The two species are allopatric. *Geranium canescens* is easily distinguished from *G. harveyi* by its longer sepals, white and shorter petals, glandular indumentum and discoloured leaves.

Fig. 609. *Geranium harveyi*. a, b. Habit. c. Leaf. d. Detail of the adaxial surface of the leaf. e. Detail of the abaxial surface of the leaf. f-h. Stipules. i. Bracteoles. j. Sepals. k. Petal. l. Flower without sepals and petals. m. Stamen. n. Fruit. o. Mericarp. p. Seed. (Based on: a-c, f, h, j, k, *Bengis 388*, PRE; d, e, g, i, l, m, *Hilliard & Burt 14780*, NU; n-p, *Moffett 2892*, NU).

Fig. 610. Distribution of *Geranium harveyi*.

According to Hilliard & Burt (1985: 188), some specimens of *G. harveyi* can have glandular hairs on pedicels or sepals. These specimens, which also have longer petals have been reidentified as *G. drakensbergense*, leaving *G. harveyi* as a species with eglandular indumentum. For more details see the discussion of *G. drakensbergense*.

Zeyher 447 (lectotype, designated by Hilliard & Burt 1985: 189, S-G-2848 image!; isolectotype, SAM).

*Perennial herbs*, 24-70 cm tall. *Rootstock* 2.4-2.6 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* ascending to suberect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long. *Basal leaves* unknown, cauline leaves alternate and upper opposite; leaf laminae (1.2)2-3.3(3.8) cm long, 1.4-4.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.75-0.86(0.88)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, densely covered with greyish-white, eglandular hairs on the adaxial surface, silky-canescens on the abaxial surface; segments 5, in 1 plane, middle segment rhombic,

(1.1)2.1-5.3(6.7) mm wide at the base [ratio segment width at the base/middle segment length = (0.08)0.17-0.24(0.26)], 5-11-lobed in distal half [ratio secondary sinus length/middle segment length = (0.17)0.22-0.28(0.29)]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long; stipules 3.7-8.4 mm long, 1.1-4.5 mm wide, 2-3-fid, with linear lobes 2.6-6.6 mm deep, 0.3-0.6 mm wide, free, papery, brown, with eglandular hairs on abaxial surface, ± glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.6-4.4]; peduncles (19)33-80(114) mm long, with patent to retrorse, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.2-0.8 mm long; bracteoles 2.7-6.4 mm long, 0.2-0.7 mm wide, linear-lanceolate, whorled; pedicels (22)27-34(45) mm long, with patent to retrorse, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.3-0.7 mm long. Flowers actinomorphic. *Sepals* (6.5)6.9-7.6(10) mm long, 2.2-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.4)0.5-0.9(1) mm long [ratio mucro length/sepal length = 0.07-0.12(0.14)], silky-canescens, with appressed eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.4-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.2)6.3-7.5(8.5) mm long, (3)3.2-4.4 mm wide, erect-patent, slightly emarginate (notch 0.1-0.8 mm deep), without claw, white, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments (3.4)3.9-5.8(5.9) mm long, lanceolate, unknown color, with scattered eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 0.9-1.4 mm long, unknown color. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3.8-6.2 mm long, unknown color. *Fruit* (17.4)18-

24(26.7) mm long, erect, discharge of seed-ejection type; mericarps 2.9-3.9 mm long, 1.5-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.3-1.1 mm long and patent, glandular hairs 0.4-0.9 mm long; rostrum 11.6-19.4 mm long, with a narrowed apex 1.7-2.9 mm long, not twisted, with patent, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.3-0.8 mm long; stigmatic remnants 1.2-2.4 mm long, with 5 glabrous lobes. *Seeds* 2-2.4 mm long, 1.2-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 611.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 431; Verhoeven & Venter 1992: 441, 442).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from September to November.

*Distribution*. This species ranges through southwestern Western Cape, plus an isolated locality in Northern Cape, in South Africa (Fig. 612).

*Habitat*. Dry slopes, streambanks and roadsides; 200-1550 m.

*Additional specimens examined*. **South Africa**. **NORTHERN CAPE**: Fraseburg, Riethuisies, on way from farmhouse to Spitzkop, 32°16'S, 21°27'E, 1 Apr. 1994, *Bruyns 5991* (BOL). **WESTERN CAPE**: Worcester, Du Toits Peak, 33°45'S, 19°10'E, 4 Nov. 1951, *Esterhuysen 19219* (BOL, PRE); Stellenbosch, 33°56'S, 18°52'E, Nov. 1912, *Worsdell s.n.* (K); Biesievlei, Jonkershoek, 33°57'S, 18°56'E, 11 Oct. 1945, *Rycraft 1004* (PRE); Cape Peninsula, Orange Kloof, 33°59'S, 18°23'E, Oct. 1946, *Power 32265* (BOL); Cape Peninsula, Orange Kloof, 33°59'S, 18°23'E, 16 Oct. 1932, *Salter 2821* (BM); Cape Peninsula, N slope of Vlakkenberg, 34°1'S, 18°23'E, 8 Sep. 1952, *Salter 9075* (BM, MO); farm Rustenburg, 34°2'S, 18°47'E, 6 Sep. 1946, *Strey & al. 839* (M); Caledon district, Palmiet Rivier, 34°8'S, 19°3'E, 13 Oct. 1894, *Schlechter 5419* (C, MO, Z); Keermoskloof, Salmonsdam Nature Reserve, Stanford, 34°25'S, 19°39'E, 11 Sep. 1981, *Hugo 2628* (MO); Pearl mountain, 34°39'S, 19°29'E, Oct. 1886, *Cummings 112* (NY, US).

**Discussion.** *Geranium canescens* is a perennial herb similar to *G. harveyi*, with a spreading, suberect to ascending stem. The stem is branched from the base, somewhat lignified in the lower part and naked or with the remains of stipules, apparently without rosette. However, these data should

be taken with caution because they are based on a single complete herbarium specimen [that is in agreement with the description provided by Hilliard & Burt (1985: 189)]. In contrast to *G. harveyi*, the inflorescence of *G. canescens* has glandular hairs on peduncles, pedicels, sepals

and fruits. The leaves of *G. canescens* are quite similar those of *G. harveyi* in outline and lobe division, but as stated by Hilliard & Burt (1985: 188) they are “more markedly discolorous than those of *G. harveyi* and the indumentum is thinner (the leaf blade is often visible through the hairs on the lower surface)”. On the upper surface the indumentum is also less dense than in *G. harveyi*. The stipules of *G. canescens* are bifid or trifid with narrow and deep lobes. Additional differences between *G. canescens* and *G. harveyi* are the longer sepals, shorter and white petals of the former. The specimen *Bruyns 5991* (BOL) has a less dense indumentum on the abaxial surface but otherwise fit well with *G. canescens*.

Hilliard & Burt (1985: 189) designated the lectotype of *G. canescens* on the herbarium G-DC, but did not indicate which specimen of the three included in the “microfiche 246” was the type. One of these specimens is G-DC-00214926 that, according to N. Fumeaux (*in litt.*), has the annotation of “Prom. bon. spei Thunberg” on the back of the sheet, and, the annotation of “*G. canescens* Lh” on the front, handwritten by L’Héritier. Furthermore, it seems to be used to prepare the drawing mentioned in the prologue (L’Héritier 1792, tab. 38). Consequently, I selected such specimen as lectotype in second step.

*Discussion*. *Geranium drakensbergense* is a perennial herb with a suberect to ascending stem, branched from the base. The branch bases are usually naked or with the remains of stipules and petioles, and ending sometimes in tufts of leaves. The leaf lamina is deeply palmatifid but the divisions do not reach the base.

*Geranium drakensbergense* is also well characterized by its long and wide petals and the glandular indumentum of the inflorescence.

The stem and petioles of *G. drakensbergense* are covered by sparse appressed, retrorse, eglandular hairs. Some specimens (i.e.: Hilliard and Burt 9007, K, NU), however, are less hairy below, but otherwise fit

patent, glandular hairs, especially on pedicels and sepals. The leaves are usually discolour, covered by sparse appressed eglandular on the adaxial surface and sericeous on the abaxial surface. Some specimens (i.e.: Hilliard and Burt 9007, K, NU), however, are less hairy below, but otherwise fit

well with the type, as noted Hilliard & Burt (1985: 191).

Around of Bosberg, some 500 km southwest of the range of *G. drakensbergense*, some distinctive plants grow that deserve a special comment [Hilliard & Burt 13216 (NU), Van der Walt 247 (PRE) and MacOwen 289 (K, W, WU)]. These specimens were identified by Hilliard & Burt (1985: 188) as *G. harveyi*. Although the indumentum of their leaves and stems is very similar to that of *G. harveyi*, these plants differ in several important characters, to include them in that species. They have significantly longer sepals and petals than *G. harveyi* and glandular hairs on the inflorescence (never found in *G. harveyi*). Bosberg plants could be separated from *G. drakensbergense* because they have a denser indumentum on stem and petioles, and especially on the adaxial surface of the leaf lamina. The leaf lamina is somewhat less divided than *G. drakensbergense* but with some overlap. The habit and fruit are not well known. All of these characters, however, do not seem very robust considering the variability of *G. drakensbergense*. Therefore these specimens are included here in *G. drakensbergense* with some doubts, awaiting further collections to clarify whether they deserve to be described as a new species.

Fig. 616. Distribution of *Geranium angustipetalum*.

emarginate (notch ca. 0.5 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs ca. 0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3-4 mm long, lanceolate, yellow, with eglandular hairs 0.4-0.5 mm long on the abaxial surface and margin; anthers 1.2-1.3 mm long, yellow. *Nectaries* 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 4-5 mm long, purple. *Fruit* 20-24 mm long, erect, discharge of seed-ejection type; mericarps 3.1-3.4 mm long, 1.2-1.8 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.7-1 mm long and patent, glandular hairs 0.8-1 mm long; rostrum 16.5-16.8 mm long, with a narrowed apex 2.4-2.5 mm long, not twisted, with patent, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.9-1 mm long; stigmatic remnants 2.4-2.5 mm long, with 5 glabrous lobes. *Seeds* ca. 2.3 mm long, ca. 1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 615.

*Pollen*. Ornamentation not studied.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in February.

*Distribution*. This species is endemic to KwaZulu-Natal, in South Africa (Fig. 616).

*Habitat*. Grassland at the foot of moist cliffs; 2300-2350 m.

*Discussion*. *Geranium angustipetalum* is a rare species known only from the type locality. This species is very similar to *G. drakensbergense*, from which it can be differentiated by the characters indicated below. *Geranium angustipetalum* has leaves a bit less divided with the middle segment wider at the base. Its sepals and petals are shorter and the latter narrower. In addition, the glandular hairs of the inflorescence, especially those of the sepals, are finer and longer than those of *G. drakensbergense*.

It would be useful to have more collections to know the variability of *G. angustipetalum* and check if the traits on which it is based are stable or if it could be included in the variability of *G. drakensbergense*. Until there are more collections, *G. angustipetalum* is recognized here with some doubts. It is interesting to note that *G. drakensbergense* is common in the area and has been collected in the same locality where *G. angustipetalum* has been described.

Despite its name, the petals of *G. angustipetalum* are not as narrow like those of *G. wakkerstroomianum*. *Geranium brycei*, with which it has sometimes been compared, is a much more robust plant, with larger, more deeply divided leaves that have a characteristic abaxial surface indumentum, and longer sepals and petals.

#### 244. *Geranium ornithopodioides*

(holotype, NU-0015566-0; isotype, E-00200412!).

*Perennial herbs*, 32-58 cm tall. *Rootstock* 3-4 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* climbing, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 1.5-2.6 mm long and patent, glandular hairs 0.6-1.8 mm long. *Basal leaves* in a deciduous rosette, cauline leaves alternate and upper opposite; leaf laminae (5.4)5.8-8.6(9.8) cm long, 5.9-10.6 cm wide, peltate, palmatifid [ratio main-sinus length/middle segment length = (0.59)0.62-0.70 (0.71)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs on the adaxial surface and with  $\pm$  long, spread, eglandular hairs, abaxially; segments 5, in 1 plane, middle segment rhombic, (12.6)13.4-18.9(21.1) mm wide at the base [ratio segment width at the base/middle segment length = (0.25)0.26-0.32], 7-11-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.14-0.16]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 1.9-2.4 mm long and patent, glandular hairs 0.7-1.5 mm long; stipules 8.1-11 mm long, 4.6-6.9 mm wide, 3-5-fid, with linear lobes 4.8-9 mm deep, 0.6-1.5 mm wide, free, papery, brown, with eglandular hairs on abaxial surface,  $\pm$  glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1-2.2]; peduncles (27)30-71(90) mm long, with patent, eglandular hairs 1.1-2.5 mm long and patent, glandular hairs 0.8-1.6 mm long; bracteoles 4.4-5.9 mm long, 0.7-1 mm wide, linear-lanceolate, whorled; pedicels (10)14-22(23) mm long, with patent, eglandular hairs 0.5-2.3 mm long and patent, glandular hairs 1.1-1.8 mm long. Flowers actinomorphic. *Sepals* 6.5-8.3(9.2) mm long, 2.7-4.9 mm wide, lanceolate, smooth, not ac-

crescent, nerves 3, mucro 0.8-1.2(1.3) mm long [ratio mucro length/sepal length = 0.09-0.20], with  $\pm$  appressed, eglandular hairs 0.2-0.9 mm long and patent, glandular hairs 1-1.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (10.2)10.4-11.2(11.6) mm long, (5.2)5.3-6.2(6.4) mm wide, erect-patent, rounded, without claw, pink, hairy on the base of the adaxial

surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.5-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.3-6.8 mm long, lanceolate, unknown color, with eglandular hairs 0.2-0.3 mm long on the abaxial surface and margin; anthers 1.7-1.9 mm long, unknown color. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 6.8-7.3 mm long,

unknown color. *Fruit* 27-31 mm long, erect, discharge of seed-ejection type; mericarps 4.5-4.6 mm long, 1.9-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black, with erect-patent, eglandular hairs 1.8-2.3 mm long and usually, patent, glandular hairs 0.6-1.1 mm long; rostrum 20-24 mm long, with a narrowed apex 3.5-4.3 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.2 mm long and  $\pm$  patent, glandular hairs 0.6-1.1 mm long; stigmatic remnants 1.6-2.1 mm long, with 5 hairy lobes. *Seeds* 2.7-2.8 mm long, 2.3-2.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 617.

*Pollen*. *Geranium*-type (Verhoeven & Venter 1992: 441, 442).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in October.

*Distribution*. This species is endemic to KwaZulu-Natal, in South Africa (Fig. 618).

*Habitat*. Grassland and edge of forest paths; 450-600 m.

*Additional specimens examined*. **South Africa**. KWAZULU-NATAL: Pinetown distr., Krantz kloof, 29°44'S, 30°50'E, Oct. 1921, Haygarth 22749 (PRE); Krantz kloof Nature Reserve, above Nkutu Gorge, 29°44'S, 30°50'E, 26 Oct. 2001, Styles 70 (NU).

Fig. 618. Distribution of *Geranium ornithopodioides*.

*Discussion.* *Geranium ornithopodioides* is a climbing herb that leans back on the surrounding vegetation. It has a weak vertical rootstock branching from the base into multiple aerial stems. The shape of its leaves resembles that of *G. ornithopodon*, except for a detail of great importance: the petiole is attached near the center of the blade, not at the margin as is the case in the rest of the known species of *Geranium*. *Geranium ornithopodioides* is also distinguished by a peculiar indumentum comprised of soft, long and patent, eglandular hairs, especially on the stem, petioles, peduncles and pedicels, which are accompanied by other somewhat shorter glandular hairs. These long, soft, eglandular hairs are also found on the abaxial surface of the leaves, where no glandular hairs have been observed.

According Scott-Shaw & von Staden (2007) there are three locations for this species, two inside the boundaries of Kranszkloof Nature Reserve and other in Umzinto district. The latter is an excessively transformed area where the presence of surviving specimen needs to be confirmed.

**245. *Geranium baurianum* R. Knuth** in Engl., Pflanzenr. IV.129 (Heft 53): 156. 1912. TYPE LOCALITY: "Kapland: Barzija, 1000 m (R. Baur, Austro-Afric. n. 182! -- Typus in herb. Berol.). -- Blühend Mai". TYPE: South Africa. Eastern Cape, Kapland, Baziya, 31°33'S, 28°25'E, R. Baur 182 (holotype, B destroyed). South Africa. Eastern Cape, Baziya Mt., 31°33'S, 28°25'E, 10 Feb. 1981, O.M. Hilliard & B.L. Burtt 13907 (neotype, here designated, K!; isoneotype, NU-0089048!).

*Perennial herbs*, 21-42 cm tall. *Rootstock* 4.8-13.4 mm in diameter, ± vertical, not tuberculate, turnip-shaped, with thickened roots along the rootstock. *Stem* procumbent to ascending, leafy, not rooting at nodes, stolons absent, without vegetative

stems, with patent to retrorse, not appressed, eglandular hairs 0.5-1.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves alternate and upper opposite; leaf laminas (1.7)2.2-3.8(4.9) cm long, 1.5-5.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.28)0.32-0.43(0.47)], suborbicular in outline, base cordate, not coriaceous, with nerves not projected, subglabrous or with scattered, spread, eglandular hairs on the adaxial surface and with ± abundant, spread, eglandular hairs abaxially; segments 5, in 1 plane, middle segment obtriangular, (7)10.1-15.6(19.9) mm wide at the base [ratio segment width at the base/middle segment length = (0.50)0.58-0.75(0.78)], 5-8(9)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.05)0.10-0.13(0.14)]; petioles up to 9 cm long, without abscission zone, terete, not swollen, not deflexed in age, with ± patent, eglandular hairs 0.2-1.4 mm long; stipules 3.8-6.3 mm long, 2-5.7 mm wide, (2)5-6-fid, with linear lobes 2.5-4.8 mm deep, 0.4-0.8 mm wide, free, papery, brown, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.5)3-4(4.5)]; peduncles (20)22-48(91) mm long, with patent, eglandular hairs 0.4-1.1 mm long; bracteoles 3.7-6.1 mm long, 0.5-1.1 mm wide, linear-lanceolate, whorled; pedicels (11)14-30(47) mm long, with patent, eglandular hairs 0.4-1.1 mm long. Flowers actinomorphic. *Sepals* (6.2)7.1-7.9(9.4) mm long, 2.6-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.6)0.7-1.1(1.5) mm long [ratio mucro length/sepal length = (0.09)0.11-0.13(0.23)], with ± patent, eglandular hairs 0.6-1.1 mm long and, rarely, patent, glandular hairs 0.7-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (11.5)13.1-14(14.8) mm long, (6.3)6.5-8.1(9) mm wide, erect-patent, slightly emarginate (notch 0.3-1.3 mm deep), without claw, pale pink to light pur-

ple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments (3.7)4.7-5.6(5.7) mm long, lanceolate, yellow, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.5 mm long; anthers (1.3)1.4-1.5(1.7) mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.4-6.6 mm long, yellow. *Fruit* (17)22.4-18.2(20) mm long, erect, discharge of seed-ejection type; mericarps 2.7-3.5 mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black, with erect to patent, eglandular hairs 0.4-0.9 mm long; rostrum 11-15.6 mm long, with a narrowed apex 1.9-3.1 mm long, not twisted, with ± patent, eglandular hairs 0.4-0.7 mm long and, rarely, scattered ± patent, glandular hairs 0.4-0.5 mm long; stigmatic remnants 1.9-2.7 mm long, with 5 glabrous lobes. *Seeds* 2.2-2.4 mm long, 1.4-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 619.

*Pollen.* *Geranium*-type (Verhoeven & Venter 1992: 440, 442).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from October to February.

*Distribution.* This species ranges from central Eastern Cape to southern KwaZulu-Natal, in South Africa (Fig. 620).

*Habitat.* Moist grassy mountain slopes, rocky grassland and forest edges; 0-1700 m.

*Additional specimens examined. South Africa.* Afr. Austr., Drège s.n. (K). **Discussion.** *Geranium baurianum* is easily recognized by its suborbicular leaves, shallowly divided and shortly petiolate or sessile on the medium and upper part of the shoot. The indumentum is predominantly eglandular. Some specimens can have glandular hairs on sepals, but not in all fragments of the collection. The indumentum of the leaves varies considerably in density. In buds or when young the leaves can be whitish because the dense indumentum. Normally the leaf lamina is subglabrous adaxially, with some hairs towards the margin, but some specimens have scattered to quite densely spread hairs all over the surface. On the abaxial surface the indumentum is more dense but never sericeous. The stipules are flabellate in outline usually with 5-6, linear, deep lobes but, trifid stipules sometimes appear in some nodes. The rootstock is vertical and carrot-like, although not as thick as in some species from Australia and South America. The rootstock bears

Fig. 620. Distribution of *Geranium baurianum*.

several lateral thickened roots as well as other thin roots.

The holotype of *G. baurianum* was lost during the Berlin fire at 1943. No duplicate has been located in K, GRA, NU or PRE herbaria. Consequently, a neotype has been proposed from the Baur's original locality.

*Geranium baurianum* has sometimes been compared to *G. contortum* from which it is distinguished by its much less deeply divided leaves and its turnip-shaped rootstock. Additionally, *G. baurianum* has more divide stipules, shorter peduncles, and usually an eglandular indumentum.

**Discussion.** *Geranium amatolicum* is a perennial herb with a spreading stem suberect to ascending. The stem is branched from the base, somewhat lignified in the lower part and naked or with the remains of stipules, apparently without rosette. According to Hilliard & Burt (1985: 213) some specimens spread by means of over-ground stems (not rooting). This is not easy to check on herbarium sheets. Noticeably, the specimen *Stirton* 6258 (PRE) is a fragment of a very robust plant, perhaps a subshrub. This is another example of how the habit and the underground parts of South African cranesbills are still poorly understood. The leaves of *G. amatolicum* are palmatifid and not deeply divided, the petals and the sepals are long, and the long sepal mucro is strongly characteristic. The indumentum of *G. amatolicum* is very variable. The specimens with long glandular hairs mixed with shorter ones, glandular and eglandular, are the most frequent. Sometimes the long glandular hairs disappear or become infrequent in some parts of the plant (for instance on the leaf lamina). As Hilliard & Burt (1985: 213) noted, it is more frequent on plants from Hogsback area, but it

occurs in different combinations that seem unstable. These authors indicated that it may be no more than a local form, which seems correct.

*Geranium amatolicum* is easy to differentiate from *G. schlechteri* by its larger petals and by the long mucro of the sepals. The former has a restricted and allopatric distribution in relation to the latter, that is distributed more northwards.

**247. *Geranium grandistipulatum*** Hilliard & B.L. Burt, Notes Roy. Bot. Gard. Edinburgh 42(2): 213, 174 fig. 2 l. 1985. TYPE LOCALITY: "E Cape, Stutterheim distr., W end of Kabaku Hills, 19 ix 1942, Acocks 9089 (PRE holo.)". TYPE: South Africa. Eastern Cape, Stutterheim distr., W end of Kabaku Hills, 32°31'S, 27°26'E, 19 Sep. 1942, J.P. Acocks 9089 (holotype, PRE-0663524-0 image!).

Perennial herbs or subshrubs, 18-41 cm tall. Rootstock and roots unknown. Stem ascending to erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.7-1.4 mm long and, usually, patent, glandular hairs ca. 1 mm long. Basal leaves unknown, cauline leaves alternate and upper opposite; leaf laminae 3.3-5.4 cm long, 3.8-7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.76], polygonal in outline, base cordate, not coriaceous, with nerves not projected, usually with  $\pm$  appressed, eglandular and glandular hairs on both surfaces, sometimes lacking glandular ones; segments 5, in 1 plane, middle segment rhombic, 4.6-13.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.21-0.40], 15-33-lobed in distal half [ratio secondary sinus length/middle segment length = 0.13-0.30]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-1.4 mm long and usually, patent, glandular hairs 0.3-0.8 mm long; stipules

3.5-14.3 mm long, 1.9-6.6 mm wide, 2-3-fid, with lanceolate lobes 1.7-8.2 mm deep, 1.4-2.2 mm wide, free, papery, brown, with eglandular hairs on abaxial surface,  $\pm$  glabrous adaxially. Inflorescence a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.3-2.9]; peduncles 30-84 mm long, with patent, eglandular hairs 0.2-1.6 mm long and usually, patent, glandular

hairs ca. 1.2 mm long; bracteoles 3.6-9.6 mm long, 1.4-1.7 mm wide, lanceolate, whorled; pedicels 9-21 mm long, with patent, eglandular hairs 0.4-1.1 mm long and patent, glandular hairs 0.3-1.2 mm long. Flowers actinomorphic. Sepals 6.7-10.1 mm long, 2.8-4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1-1.5 mm long [ratio mucro length/sepal length = 0.16-0.18], with  $\pm$  patent, eglandu-

lar hairs 0.4-0.8 mm long and, patent, glandular hairs 0.3-0.4 mm long on the abaxial surface, glabrous adaxially. *Petals* 14.3-18.9 mm long, 10-13.9 mm wide, erect-patent, rounded or emarginate (notch ca. 2.5 mm deep), without claw, rose pink, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.2-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.8-8.2 mm long, lanceolate, unknown color, with eglandular hairs 0.3-0.5 mm long on the abaxial surface and margin; anthers ca. 1.8 mm long, unknown color. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 4-5 mm long, unknown color. *Fruit* 25-26 mm long, erect, discharge of seed-ejection type; mericarps ca. 3.3 mm long, ca. 1.7 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with erect-patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.8-0.9 mm long; rostrum 18-19 mm long, with a narrowed apex 4-5 mm long, not twisted, with patent, eglandular hairs 0.3-0.4 mm long and patent, glandular hairs 0.7-0.8 mm long; stigmatic remnants 2.2-2.3 mm long, with 5 glabrous lobes. *Seeds* unknown. Cotyledons not studied. Fig. 623.

*Pollen*. *Geranium*-type (Verhoeven & Venter 1992: 441, 442).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from September to November.

*Distribution*. This species is endemic to Eastern Cape, in South Africa (Fig. 624).

*Habitat*. Grassland and forest clearings and among stones; 1000-2050 m.

*Additional specimens examined*. **South Africa**. EASTERN CAPE: Maclear, Bastervoeypad, farm Snowy Side, 27 km NNW of Ugie, 31°8'S, 27°59'E, 17 Nov. 1993, Bester 1712 (PRE); Transkei, road from Umtata towards Port St. Johns, Misty Mountain, 31°32'S, 28°56'E, 6 Nov. 1985, Gibby & Crompton 162 (BM).

*Discussion*. *Geranium grandistipulatum* is a rare species infrequently collected, of which only two samples have been obtained on loan, in addition to the image of the type. With these samples it has been difficult to accurately determine the variability of the species and to prepare a more detailed description, especially as regards the subterranean parts and the fruit. Nevertheless, *Geranium grandistipulatum* is very well characterized against the rest of the South African species by its stipules, whose divisions are shallow and relatively wide. Its leaves are shallowly divided and its indumentum variable in the few samples examined. The bracteoles appear somewhat wider than in other species in the region. It is differentiated from *G. amatolicum* by its shorter sepal mucro.

**Discussion.** *Geranium schlechteri* is a perennial herb with a long, spreading, procumbent stem that reach 2 m in length. The stem is branched from the base, where it is naked and with the remains of stipules. The short and vertical rootstock is in some specimens thin and without thickened roots while in others is more robust and with thickened roots. Probably the former correspond to young specimens. However, there are not enough specimens collected with the underground parts to clarify this trait. *Geranium schlechteri* is easily distinguished by its palmatipartite leaves, not deeply divided, clothed with soft glandular hairs on the abaxial surface, its 2-3-fid stipules, its short sepals and petals. The indumentum of *G. schlechteri* comprises both glandular and eglandular hairs. Long and soft glandular hairs are usually very dense on stems, petioles and inflorescence

and are found less densely throughout the plant, although they are sometimes rare on the adaxial surface of the leaves.

Laundon (1961: 62) described *G. exellii* based on three collections from the border between Mozambique and Zimbabwe, about 900 km north of the northernmost known localities of *G. schlechteri*. This author considered that the cut of the leaf, somewhat more divided, is an important feature to differentiate *G. exellii* from *G. schlechteri*, in addition to other minor characters. These collections show slightly more divided leaves than is usual, but otherwise fall within the range of variation encompassed by my concept of *G. schlechteri*.

**249. *Geranium contortum*** Eckl. & Zeyh., Enum. Pl. Afric. Austral. 1: 59. 1834-35. TYPE LOCALITY: "Ad declivitates gramineas montis 'Winterberg' altit. V (Kafferland). Dec.". TYPE: South Africa. axial surface,  $\pm$  glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.6)2.5-4.4(4.9)]; peduncles (17)47-77(93) mm long, with patent to retrorse, eglandular hairs 0.2-1.5 mm long and, usually, patent, glandular hairs 0.2-0.5 mm long; bracteoles 4.9-8.5 mm long, 0.4-0.8 mm wide, linear-lanceolate, whorled; pedicels (17)30-42(44) mm long, with patent to retrorse, eglandular hairs 0.4-1.3 mm long and, usually, patent, glandular hairs 0.3-1.2 mm long. Flowers actinomorphic. *Sepals* (7.3)7.6-8.4(8.7) mm long, 2.4-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.9)1-1.3(1.4) mm long [ratio mucro length/sepal length = (0.11)0.13-0.17 (0.19)], with appressed to  $\pm$  patent, eglandular hairs 0.3-0.8 mm long and, usually, patent, glandular hairs 0.1-0.3 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.6)13.2-15.8(18.2) mm long, (6.5)7.9-11(16.6) mm wide, erect-patent, emarginate (notch 0.7-2.3 mm deep) or, rarely, rounded, without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5)5.2-5.6(5.7) mm long, lanceolate, yellow, with scattered eglandular hairs 0.2-0.5 mm long on the abaxial surface and margin; anthers (1.8)1.9-2.2 mm long, unknown color.

Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 4.1-6.7 mm long, unknown color. *Fruit* 25.1-28.8(30.6) mm long, erect, discharge of seed-ejection type; mericarps 2.8-4 mm long, 1.5-2.1 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.2-1.2 mm long and patent, glandular hairs 0.2-0.4 mm long; rostrum 17.9-22.8 mm long, with a narrowed apex 1.8-3.5 mm long, not twisted, with  $\pm$  patent, eglandular hairs 0.1-0.7 mm long and patent, glandular hairs 0.2-0.4 mm long; stigmatic remnants 2.6-3.7 mm long, with 5 glabrous lobes. *Seeds* 2.6-2.8 mm long, 1.7-1.8 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 628.

*Pollen.* *Geranium*-type (Verhoeven & Venter 1992: 441, 442).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from December to January.

*Distribution.* This species ranges through central Eastern Cape, in South Africa (Fig. 629).

*Habitat.* Damp grassland; 1400-1950 m.

*Additional specimens examined.* **South Africa.** EASTERN CAPE: 25 km from cala turn off on road to Engcobo, 31°32'S, 27°51'E, 12 Jan. 1997, *Bredenkamp* 1138 (PRE); Cathcart, Windvogelberg, 32°17'S, 27°6'E, 8 Dec. 1981, *Hilliard & Burt* 14782 (E, NU, PRE); Bedford district, farm Quaggashoek, at Telkom tower, 32°19'S, 26°21'E, 19 Jan. 2016, *Steyn* 2240 (PRE); Seymour, summit of Nico Malan Pass, 32°30'S, 26°49'E, 22 Jan. 1990, *Edwards* 724 (NU, BOL); Stutterheim district, Thomas Mountain, 32°34'S, 27°14'E, 9 Dec. 1981, *Hilliard & Burt* 14797 (E, NU); without locality, Dec. 1917, *Ratray* 47 (PRE).

*Discussion.* *Geranium contortum* is a small plant, with a long thin and  $\pm$  horizontal rootstock. The stem is branched from the base, somewhat lignified in the lower part. At the apex of each branch the leaves are crowded, but apparently without forming a

rosette, becoming distant upwards. The indumentum of *G. contortum* is highly variable. Specimens with both glandular and eglandular hairs, are the most frequent. Sometimes the glandular hairs disappear or become infrequent in some parts of the stem, petiole, leaf lamina or even on the inflorescence.

*Geranium contortum* is easy to differentiate from *G. schlechteri* by its longer sepals and petals, and the lack of the long, soft glandular hairs characteristic of the latter. *Geranium ornithopodon* also has shorter sepals, a very different leaf cut, and lacks glandular hairs.

**Discussion.** *Geranium ornithopodon* is a perennial herb with a spreading stem, ascending to suberect. The total length is unknown since only fragments are represented in the collections studied. The only specimen available with basal and underground parts (*Hilliard & Burtt* 13485, M, NU) has a stem branched from the

base, not lignified in the lower part and naked or with the remains of stipules, apparently without rosette, and with a separated rootstock fragment which is difficult to interpret. The leaves of *G. ornithopodon* are palmatifid, not deeply divided, and paler but not sericeous below. The middle leaf segment shows a characteristic outline with 1-2(3) well marked, spread lobes on each side (usually with additional lobelets) and with  $\pm$  parallel sides below the lower lobes (sometimes slightly obcuneiform).

The inflorescence usually has an indumentum of both glandular and eglandular hairs, although in some specimens glandular hairs are scarce, while on petioles and stem glandular hairs are very rare. According to *Hilliard & Burtt* (1985: 217-220) *G. ornithopodon* has been traditionally characterized by its spread hairs versus the appressed ones of *G. flanaganii*. These authors analyze the variability and geographic distribution of the indumentum and correctly conclude that these species cannot be differentiated by the density or position of its eglandular hairs. However, *Hilliard & Burtt* (1985: 217-220) consider that *G. ornithopodon* is a species of short sepals and petals, which extends over Western Cape and Eastern Cape and accept *G. flanaganii* as an independent species because of its longer sepals

Fig. 630. *Geranium ornithopodon*. a. Habit. b. Leaf. c. Stipules. d. Bracteoles. e. Sepal. f. Petal. g. Fruit. h. Mericarp. (Based on: a, c, *Hilliard & Burtt* 13485, M; d, e, *Pegler* 1158, BM; b, *Hilliard & Burtt* 6835, NU; f, h, *Hilliard & Burtt* 6833, NU; g, *Salter* 7026, BOL).

Fig. 631. Distribution of *Geranium ornithopodon*.

and petals. The latter ranges from southernmost Swaziland through Natal to Eastern Cape. They indicate a list of specimens difficult to include in *G. flanaganii* and suggest that hybridization may have played an important role in the variability found in these species. Hilliard & Burt (1985: 217-220) were very aware of the difficulties of their proposal to fit this difficult group of geraniums into a taxonomic system.

In the present study, it has been found that the plants from Western Cape consistently have small flowers but those of Natal are highly variable, in general with some longer sepals and petals but with a wide overlap. A great variability in these characters that does not show geographic tendencies has been found throughout the Eastern Cape. Variability has also been found within the same specimens. For example, in *Ecklon & Zeyher 449* (SAM) (isolectotype of *G. ornithopodon*), a flower has sepals of c. 4.5 mm and another of 5.9-6 mm. In fact, if the differentiation criteria proposed by Hilliard & Burt (1985: 217-220) were applied, it would be difficult to attribute many specimens to one of the two species with certainty. It is obvious, however, that the synonymization of *G. flanaganii* that is proposed here is not a completely satisfactory solution that perhaps can be amended with a more in-depth study.

Hilliard & Burt (1985: 216) indicated as type of *G. ornithopodon* the number "*Ecklon & Zeyher 443*". This is probably a mistake. In SAM-0030063A-0 there is a label in Hilliard's hand that states "Isotype" for this sheet numbered as "449". The specimen S-G-2851 is a sterile branch of *Ecklon & Zeyher 449*. On the same sheet there is a specimen of *G. wakkerstroonianum* collected by Drège, well separated (numbered S-07-8947) and with an identification label in Hilliard and Burt's hand. S-07-8946 is a single leaf of *Ecklon & Zeyher 449*. To clarify the matter, I think that S-G-2851 should be proposed as lectotype in second-step.

*Perennial herbs*, (18)27-75(100) cm tall. *Rootstock* 3.5-4 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* procumbent to ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.4-1.7 mm long. *Basal leaves* not present (no rosette), cauline leaves alternate and upper opposite; leaf laminae (1.6)1.8-5.3(7) cm long, 1.8-7.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.69)0.71-0.82], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± appressed, eglandular hairs on both surfaces, sometimes densely on the abaxial surface; segments 5, in 1 plane, middle segment rhombic, (2.4)3.4-10(14.7) mm wide at the base [ratio segment width at the base/middle segment length = (0.19)0.20-0.28(0.40)], 7-13(19)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.14)0.15-0.20(0.24)]; petioles up to 22 cm long, without abscission zone, terete, not swollen, not deflexed in age, with ± patent, eglandular hairs 0.4-1.6 mm long; stipules 3.2-8.3 mm long, 1.1-4.3 mm wide, 2-3-fid, with

linear lobes 2.6-6.2 mm deep, 0.4-0.6 mm wide, free, papery, brown, with eglandular hairs on abaxial surface, ± glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.4)1.7-3(5.5)]; peduncles (23)40-53(58) mm long, with patent, eglandular hairs 0.2-1.2 mm long and, rarely, patent, glandular hairs 1-1.3 mm long; bracteoles 2.3-5 mm long, 0.2-0.7 mm wide, linear-lanceolate, whorled; pedicels (12)18-27(46) mm long, with patent, eglandular hairs 0.2-1.3 mm long and, rarely, patent, glandular hairs 1-1.3 mm long. Flowers actinomorphic. *Sepals* (5)5.1-6.6(7) mm long, 1.7-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.6)0.8-1.2 mm long [ratio mucro length/sepal length = (0.12)0.15-0.19(0.22)], with ± patent, eglandular hairs 0.4-1.6 mm long and, rarely, patent, glandular hairs 0.8-1.3 mm long on the abaxial surface, glabrous adaxially. *Petals* (7.2)9.6-11.5(12.2) mm long, (2.4)3.7-4.3(5) mm wide, erect-patent, emarginate (notch 0.8-2.1 mm deep), without claw, white or pink, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments (5.1)5.4-5.9(6.3) mm long, lanceolate, white, with scattered eglandular hairs 0.1-0.4 mm long on the abaxial surface and margin; anthers (1.1)1.3-1.5(1.6) mm long, blue. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.3.7.4 mm long, pink. *Fruit* 18.4-20.5(27.8) mm long, erect, discharge of seed-ejection type; mericarps 2.6-3.4 mm long, 1.3-2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black, with ± patent, eglandular hairs 0.5-1.1 mm long and, rarely, patent, glandular hairs 1-1.3 mm long; rostrum 12.4-21.7 mm long, with a narrowed apex 2.5-5.6 mm long, not twisted, with patent, eglandular hairs 0.2-0.7 mm long and, rarely, patent, glandular

hairs 1-1.5 mm long; stigmatic remnants 1-2.7 mm long, with 5 glabrous lobes. *Seeds* 2-2.4 mm long, 1.2-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 632, 633.

*Pollen*. *Geranium*-type (Verhoeven & Venter 1992: 441, 442).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from Eastern Cape to Limpopo, in South Africa (Fig. 634).

*Habitat*. Grassy slopes, damp sheltered places around rocks and on the edge of forest patches, or in marshy grassy places; 350-2600 m.

**Discussion.** *Geranium wakkerstroomianum* is a perennial herb with a spreading stem, procumbent to ascending. The stem is branched from the base, somewhat lignified in the lower part and naked or with the remains of stipules, apparently without rosette. Its underground parts are poorly known owing to the scarce

herbarium material available, but in some specimens a thin vertical rootstock appears. Hilliard & Burt (1985: 208), however, stated that *G. wakkerstroomianum* has a thickened taproot, which has not been confirmed in the specimens studied. This species has palmatifid leaves, similar to those of *G. ornithopodon*, not deeply divided, with an indumentum of eglandular hairs sometimes more dense on the abaxial surface, but not so dense as to be considered sericeous. Most of the specimens have only eglandular hairs on the inflorescence, but occasionally glandular hairs are also found, and very rarely there are specimens which are nearly glabrous.

*Geranium wakkerstroomianum*, which has sometimes been confused with *G. ornithopodon*, is easily identified by its narrow petals (in absolute terms and in relation to their length) which are markedly emarginate. This trait, which distinguishes it from all the species in the section, is sometimes difficult to observe in herbarium specimens if the flowers are not carefully prepared.

*Perennial herbs*, 23-80 cm tall. *Root-stock* 3-3.5 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* ascending to suberect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-0.7 mm long and rarely, patent glandular hairs 0.2-0.3 mm long. *Basal leaves* not present (no rosette), cauline leaves alternate and upper opposite; leaf laminae (2)3.7-5.4(6.4) cm long, 2.1-8.8 cm wide, not peltate, deeply palmatifid to palmatisect [ratio main-sinus length/middle segment length = (0.90)0.94-0.98(0.99)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on the adaxial surface and with appressed, eglandular hairs restricted to the nerves abaxially; segments 5, in 1 plane, middle segment rhombic (with linear-lanceolate lobes, (1.2)2.2-3.5(7.1) mm wide), (0.5)0.9-2(3.5) mm wide at the base [ratio segment width at the base/middle segment length = (0.03)0.04-0.07(0.09)], 5-18-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.24-0.27(0.57)]; petioles up to 17 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-0.6 mm long and rarely, patent glandular hairs 0.2-0.3 mm long; stipules 2.6-9.3 mm long, 0.8-3.8 mm wide, 2-3-fid, with linear lobes

1.2-7.1 mm deep, 0.4-1 mm wide, free, papery, brown, with eglandular hairs on abaxial surface,  $\pm$  glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = (1.6)1.8-3.1(6.5)]; peduncles (24)29-63(97) mm long, with retrorse, appressed, eglandular hairs 0.2-0.5 mm long and rarely, patent glandular hairs 0.2-0.3 mm long; bracteoles 1.1-4.9 mm long, 0.3-1 mm wide, linear-lanceolate, whorled; pedicels (7)9-20(31) mm long, with retrorse, appressed, eglandular hairs 0.1-0.5 mm long and usually, patent glandular hairs 0.2-0.4 mm long. Flowers actinomorphic. *Sepals* (5.1)5.3-5.9(7.7) mm long, 1.9-2.8 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.3)0.8-1(1.2) mm long [ratio mucro length/sepal length = (0.06)0.12-0.17 (0.21)], with appressed, eglandular hairs 0.1-0.4 mm long and, usually, patent, glandular hairs 0.1-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* (6.5)7.5-10.5(15.1) mm long, (3.1)3.9-7(8.6) mm wide, erect-patent, rounded or slightly emarginate (notch 0.3-0.6 mm deep), without claw, usually white, sometimes pale pink, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments (4)5.2-5.7(7.4) mm long, lanceolate, yellow, with eglandular hairs 0.1-0.3 mm long on the abaxial surface and margin; anthers (0.8)1.1-1.3(1.7) mm long, yellow. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3.9-7.8 mm long, purple. *Fruit* (20.9)23-26(26.9) mm long, erect, discharge of seed-ejection type; mericarps 3-3.6 mm long, 1.7-2.2 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callus, without a basal prong, black, with  $\pm$  patent, eglandular hairs 0.6-1 mm long and, usually, patent, glandular hairs 0.3-0.7 mm long; rostrum 14.5-20.4 mm long, with a narrowed apex 2.6-4.6 mm long, not twisted, with  $\pm$

patent, eglandular hairs 0.1-0.4 mm long and, usually, patent, glandular hairs 0.2-0.5 mm long; stigmatic remnants 1.9-2.9 mm long, with 5 hairy lobes. *Seeds* 1.7-2.4 mm long, 1.3-1.7 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 635.

*Pollen*. *Geranium*-type (Verhoeven & Venter 1992: 446).

*Chromosome number*.  $2n = 22$  (M. Gibby, in sched.).

*Phenology*. Collected in flower from October to April.

*Distribution*. This species ranges from Western Cape through Eastern Cape and KwaZulu-Natal to Mpumalanga, in South Africa (Fig. 636).

*Habitat*. Coastal grassland, roadsides, around marshes or along streambanks; 50-1900 m.

**Discussion.** *Geranium caffrum* is a perennial herb with a spreading stem, suberect to ascending. The stem is branched from the base, somewhat lignified in the lower part and naked or with the remains of stipules, apparently without rosette. Its underground parts are poorly known owing to the scarcity of herbarium material, but in some specimens a thin vertical rootstock appears. Hilliard & Burt (1985: 199), however, stated that *G. caffrum* has a long thickened taproot and a stem that roots. This has not been confirmed in the spec-

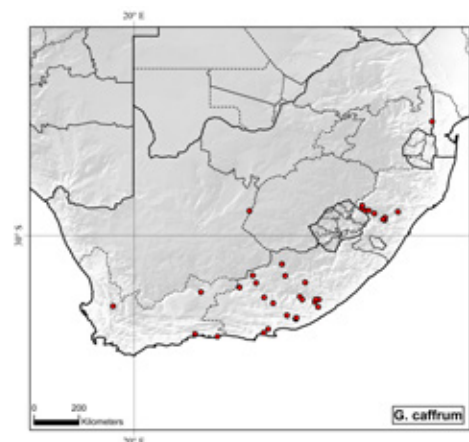

Fig. 636. Distribution of *Geranium caffrum*.

imens studied. The leaves are deeply palmatifid or even palmatisect, with narrow segments, slightly revolute on the margins. The middle segment has a narrow base and few lateral narrow lobes, the lowermost usually entire or with 1-2 teeth. The leaves are sparsely appressed-pubescent on both surfaces, but with hairs restricted to the nerves and margins on the abaxial surface, although scattered hairs can be found between the nerves exceptionally. In the most typical specimens (see the next paragraph) the stem, petiole and inflorescence indumentum is formed by appressed, eglandular hairs. It is also common to find patent, glandular hairs only on pedicels and sepals, but not in all specimens.

Hilliard & Burt (1985: 201) described *G. dregei* as a species closely allied to *G. caffrum* with smaller flowers and spreading hairs on stem, petioles and lower leaf surface. In the specimens examined (*Esterhuysen 19706*, BOL image!, PRE image!; *Flanagan 1892*, PRE; *Verdoon 1564*, PRE) there is some variation in these characters. The sepals and petals are short but fall within the variability of *G. caffrum*. Plants from Middelburg district (the type and *Verdoon 1564*) lack glandular hairs on the inflorescence and have a denser indumentum. Its eglanduliferous hairs are not clearly appressed on the stem, petiole and leaf surface, being sometimes spread. On the abaxial surface of the leaf they extend beyond the nerves while in the typical *G. caffrum* they are appressed and are restricted to the nerves. However, these indumentum characters show a certain internal variation in the studied samples, which discourages their taxonomic use without other supporting characters. With the data currently available, it seems preferable to consider *G. dregei* as a local form of denser indumentum. Further collections would be necessary to better understand the variability of these populations and eventually separate them as an independent species.

Hilliard & Burt (1985: 204) described *G. natalense* based on a collection from Karkloof forest in Natal. They also examined an additional collection from this area plus three collections by T. Cooper from Natal, without precise locality. They differentiate *G. natalense* from *G. schlechteri* by its more deeply cut leaves and by less markedly glandular indumentum. I think, however, that *G. natalense* is more closely related to *G. caffrum*. I have examined three images of the type collection and another specimen from the Karkloof forest (*Wirminghans 1051*, NU), plus *Cooper 1191* and *2047*. Cooper's collections fall well within the variability of *G. caffrum*. The type collections and *Wirminghans 1051* are, however, a bit different. They are characterized by leaves somewhat less deeply divided than the typical *G. caffrum*, and with a somewhat denser and less appressed indumentum. Nevertheless there does not appear to be any character that differentiates it conclusively. With the data currently available it seems preferable to consider *G. natalense* a local form that deserves a deeper study. Further collections would be necessary to better understand the variability of these populations and eventually separate them as an independent species.

Mary Gibby made a chromosome count of *G. caffrum*:  $2n = 22$  [based on *Gibby & Barret 462* (BM)], that remains unpublished, annotated in a small label on the voucher. She has kindly authorized me to publish it now in this monograph.

**Discussion.** *Geranium subglabrum* is a rare species, with few specimens available. Among the herbarium fragments studied none have either underground parts or seeds. According to Hilliard & Burt (1985: 202) is a "... clump-forming perennial herb, stems of indeterminate length, straggling, ...". It is quite similar to *G. caffrum* in general appearance. The leaves of *G. subglabrum* are somewhat larger and less deeply divided than *G. caffrum* (but never to be considered palmatisect). The middle segment has a base wider than in *G. caffrum*, without revolute margins and the lateral lobes are also wider and more divided. Both species share an indumentum of antrorse, appressed hairs that are restricted to the nerves and margins on the abaxial surface. In *G. subglabrum*, the indumentum of stems and petioles is only of retrorse, appressed, eglandular hairs while in *G. caffrum*, glandular hairs can sometimes be also found. On the contrary, in *G. subglabrum*, glandular hairs are always found on peduncles, pedicels and sepals, while in *G. caffrum*, some specimens lack these hairs.

The differences between *G. subglabrum* and *G. sparsiflorum* are addressed under the latter.

**Perennial herbs**, 35-51 cm tall. **Rootstock** 5.8-6.3 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. **Stem** ascending to suberect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.4-0.7 mm long and, patent, glandular hairs 1.1-1.7 mm long. **Basal leaves** in a ± persistent rosette, cauline leaves alternate and upper opposite; leaf laminae (3.2)3.6-6(7.4) cm long, 3.3-8.8 cm wide, not peltate, deeply palmatifid [ratio main-sinus length/middle segment length = (0.80)0.82-0.89(0.91)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular and sometimes glandular hairs on the adaxial surface and with ± appressed, eglandular and patent, glandular hairs usually restricted to the nerves abaxially; segments 5, in 1 plane, middle segment rhombic, (2.1)4.2-7.1(8.1) mm wide at the base [ratio segment width at the base/middle segment length = 0.11-0.18(0.19)], 7-17-lobed in distal half [ratio secondary sinus length/middle segment length = (0.23)0.24-0.43(0.47)]; petioles up to 38 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.6-1.3 mm long; stipules 3-4.7 mm long, 1.1-2.1 mm wide, 2-fid, with lanceolate lobes 1.5-2.8 mm deep, 0.6-0.8 mm wide, free, papery, brown, with eglandular and glandular hairs on abaxial surface, glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/

leaf length = 2.4-4]; peduncles 41-85(93) mm long, with ± patent, eglandular hairs 0.2-0.6 mm long and patent, glandular hairs 0.6-1.6 mm long; bracteoles 2.5-4.4 mm long, 0.6-0.9 mm wide, linear-lanceolate, whorled; pedicels (17)23-36(37) mm long, with ± patent, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.6-2.1 mm long. Flowers actinomorphic. **Sepals** (6.3)6.6-7.6 mm long, 2.1-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.5)0.6-0.9(1) mm long [ratio mucro length/sepal length = (0.09)0.10-0.13(0.14)], with appressed, eglandular hairs 0.2-0.4 mm long and patent, glandular hairs 0.9-1.7 mm long on the abaxial surface, glabrous adaxially. **Petals** 13.1-13.8 mm long, 6.8-9.1 mm wide, erect-patent, rounded, without claw, pink, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-0.6 mm long. **Stamens** 10, both whorls bearing anthers; filaments 5.6-7 mm long, lanceolate, yellow, with scattered eglandular hairs 0.2-0.4 mm long on the abaxial surface and margin; anthers 1.1-1.9 mm long, yellow. **Nectaries** 5, hemispheric, glabrous. **Gynoecium** 5.8-6.8 mm long, pale pink. **Fruit** 18-21 mm long, erect, discharge of seed-ejection type; mericarps 3.1-3.3 mm long, 1.3-1.4 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, with a basal callosity, without a basal prong, brown, with ± patent, eglandular hairs 0.4-0.5 mm long and patent, glandular hairs 1.3-1.4 mm long; rostrum 12-16 mm long, with a narrowed apex 1.7-3.1 mm long, not twisted, with ± patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.9-1.1 mm long; stigmatic remnants 2.2-2.3 mm long, with 5 hairy lobes. **Seeds** unknown. Cotyledons not studied. Fig. 639.

**Pollen.** *Geranium*-type (Verhoeven & Venter 1992: 444).

**Chromosome number.** Unknown.

**Phenology.** Collected in flower from August to March.

**Distribution.** This species ranges through northern Eastern Cape and KwaZulu-Natal, in South Africa (Fig. 640).

**Habitat.** Bog and damp grassland; 1650-2200 m.

**Additional specimens examined. South Africa.** EASTERN CAPE: Transkei, Port St. John, Mateku, 31°18'S, 29°43'E, 27 Aug.

1969, *Strey* 8967 (K); Transkei, Magwa Estates, Lusikisiki district, 31°26'S, 29°38'E, 5 Sep. 1979, *Germishuizen* 1177 (PRE). KWA-ZULU-NATAL: Alfred district, Harding, farm Bedford, 30°34'S, 29°53'E, 1 Mar. 1983, *Hilliard & Burt* 16726 (E).

**Discussion.** *Geranium sparsiflorum* is a perennial herb with a spreading, ascending to suberect stem. Its underground parts are poorly known

owing to the scarcity of available herbarium material, but in some specimens a short vertical rootstock with thickened roots appears.

The leaves of *G. sparsiflorum* are deeply palmatifid and similar those of *G. subglabrum*. Both species share leaves with a middle segment wider at the base than in *G. caffrum*, without revolute margins and with lateral lobes also wider and more divided. As in *G. caffrum* and *G. subglabrum*, the indumentum of the leaf abaxial surface of *G. sparsiflorum* is restricted mainly to the nerves. *Geranium sparsiflorum* differs from these other two species by its long, soft, glandular hairs that regularly appear on sepals, peduncles, pedicels, petioles, stem and leaves. In *G. caffrum* and *G. subglabrum* when these hairs are present, they are appreciably shorter.

*Geranium schlechteri* resembles *G. sparsiflorum* in its long glanduliferous hairs, but it is easily differentiated from the latter by its smaller, less deeply divided leaves, with hairs all over the abaxial surface, and by its shorter sepals.

Knuth (1908: 71) proposed a holotype for *G. alticola* in "herb. Schlechter", that is in B, which was destroyed. Thus Hilliard & Burt (1985: 202) rightly chose a lectotype among the available duplicates of *Schlechter* 6994. Additionally, Hilliard & Burt (1985: 202) indicated a possible labeling confusion about the type locality of

Fig. 639. *Geranium sparsiflorum*. a, b. Habit. c. Leaf. d. Stipules. e. Bracteoles. f. Sepal. g. Petal. h. Fruit. i. Mericarp. (Based on: a, *Hilliard & Burt* 16726, E; b, c, h, i, *Schlechter* 6590, G; d-g, *Schlechter* 6994, W).

Vereines Steiermark 50: 381. 1914. TYPE LOCALITY: "Proximum G. pallenti est G. tauricum\* sive G. collinum tauricum M. Bieb. Suppl. 1819 (nec 1808) et herb!.". TYPE: Russia. Ex Tauria merid., 1810, M. Bieberstein s.n. (lectotype, designated by Aedo & al. 2005b: 544, LE image!).

*Perennial herbs*, 20-51 cm tall. *Rootstock* 4-9.8 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, with thickened, fasciculate roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with retrorse, appressed, eglandular hairs 0.2-1.6 mm long and, sometimes, patent, glandular hairs 0.2-1 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae 2-5.5 cm long, 2.3-7.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.52-0.73], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5-7, in 1 plane, middle segment rhombic, 2.8-10.5 mm wide at the base [ratio segment width at the base/middle segment length = 0.20-0.36], 3-12-lobed in distal half [ratio secondary sinus length/middle segment length = 0.20-0.38]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, appressed, eglandular hairs 0.2-1 mm long and, sometimes, patent, glandular hairs 0.2-1.8 mm long; stipules 2.4-8.8 mm long, 0.9-2.6 mm wide, lanceolate to acuminate, free, papery, brownish red, with eglandular and, sometimes, glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence*

a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.1-5.2]; peduncles 17-113 mm long, with patent to retrorse, eglandular hairs 0.2-1.2 mm long and, sometimes, patent, glandular hairs 0.2-0.5(1) mm long; bracteoles 2.8-6.3 mm long, 0.4-1.1 mm wide, linear, whorled; pedicels 13.5-31 mm long, with patent to retrorse, eglandular hairs 0.2-1.2 mm long and, usually, patent, glandular hairs 0.2-0.5(0.9) mm long (mainly towards the apex). Flowers actinomorphic. *Sepals* 5.1-9.2 mm long, 1.9-3.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-1.9 mm long [ratio mucro length/sepal length = 0.12-0.36], with ± patent, eglandular hairs 0.3-0.8 mm long and patent, glandular hairs 0.3-1 mm long on the abaxial surface, glabrous adaxially (sometimes only with eglandular hairs). *Petals* 8.5-16.5 mm long, (4.8)6.1-8.5 mm wide, erect-patent, rounded to retuse, with claw 0.4-0.6 mm long, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.8 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.1-7.1 mm long, lanceolate, white with purple apex, ciliate except on the apex, with hairs 0.1-0.2 mm long; anthers 0.9-2.1 mm long, blue. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3.4-8.8 mm long, dark purple. *Fruit* 20.2-26 mm long, erect, discharge of seed-ejection type; mericarps 2-3.4 mm long, 1.3-2.5 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, without a basal callus, with a basal prong, brown, with patent, eglandular hairs 0.2-0.6 mm long and, sometimes, patent, glandular hairs 0.2-0.8 mm long; rostrum 15.2-20.9 mm long, with a narrowed apex 3.7-6.9 mm long, not twisted, with patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.4-0.8 mm long; stigmatic remnants 0.9-1.9 mm long, with 5 glabrous lobes. *Seeds* 1.6-2.1 mm long, 1.2-1.8 mm wide, reticulate, uniformly colored, brown, gla-

brous. Cotyledons with entire margin. Figs. 641, 642.

**Pollen.** *Geranium*-type (Aedo & al. 2005b: 541).

**Chromosome number.**  $2n = 24, 26, 28, 30+f$ .

**Phenology.** Collected in flower from March to August.

**Distribution.** This species ranges from southern Italy, through Balkans (Albania, Bulgaria, Serbia, North

Macedonia and Greece) to Krym, Turkey, Georgia and northwestern Syria (Fig. 643).

**Habitat.** Forests, scrub, meadows, and banks; 0-2150 m.

**Representative specimens examined.**

**Discussion.** *Geranium asphodeloides* is the most widespread of the three perennial species of the section. It is easily distinguished from *G. sintenisii* by its ± horizontal, not turnip-shaped rootstock, with thick, fleshy, fasciculate roots, and its petals (4.8)6.1-8.5 mm wide. By contrast, *G. sintenisii* has ± vertical, turnip-shaped rootstock, without thick, fleshy, fasciculate roots, and narrow petals (3.5-4.8 mm wide). Rare herbarium specimens of *G. asphodeloides* showing relatively narrow petals were collected at the end of July. These specimens also had well developed fruits. Such data suggest that extemporaneous flowering could produce smaller pet-

als, a fact that should be considered when critical specimens are identified (specimens with lower petal width). *Geranium sintenisii* consistently has glandular hairs on the stem, petioles, and inflorescence, whereas in *G. asphodeloides* glandular hairs are not always present. If present, glandular hairs are short and straight in *G. asphodeloides*, whereas they are long and a bit tortuous in *G. sintenisii*. *Geranium crenophilum* is similar to *G. asphodeloides* in rootstock, roots, and petal features, although it shows glandular hairs as described in *G. sintenisii*. *Geranium asphodeloides* varies considerably in the presence and distribution of glandular hairs. There are specimens with no glandular hairs, others with scattered glandular hairs restricted to sepal bases, or with more or less copious glandular hairs on stems and inflorescences. In some plants a part of the pedicels have glandular hairs and elsewhere none or few. Such variability does not show any geographical pattern.

Bobrov (1949) recognized from Russia two independent species related to *G. asphodeloides*: *G. tauricum* endemic to the Crimea and characterized by its indumentum of eglandular hairs, short stipules (4-5 mm long), and long petals (15-17 mm long), and *G. pallens* distributed throughout the Caucasus and characterized by its indumentum of glandular hairs, long stipules (6-8 mm long), and short petals (12-17 mm long). As discussed above, indumentum variability does not support the differentiation of any taxa from *G. asphodeloides*. In the same way, length of stipules and petals of the specimens studied from the Crimea and Caucasus fall into the variability of those characters in *G. asphodeloides*. Novoselova (1998) showed that the previously mentioned characters are quite variable in Caucasian plants, although recognized *G. pallens* as subspecies of *G. asphodeloides*.

No original specimen of *G. asphodeloides* has been located at G, where Burman herbarium is kept. Thus, a

neotype was designated from Italy, in accordance with the protologue (Aedo & al. 2005b: 543). *Geranium asphodeloides* was recorded from Iran by Parsa (1952). However, Schönbeck-Temesy (1970) included this species in “species incertae” in Iran (and I agree with this opinion), since she did not find any specimen supporting those records.

**256. *Geranium crenophilum* Boiss.,** Diagn. Pl. Orient. ser. 1, 8: 117. 1849. *Geranium asphodeloides* subsp. *crenophilum* (Boiss.) Bornm., Repert. Spec. Nov. Regni Veg. Beih. 89(3): 134. 1936. TRABZON: Lazistan, Djimil, 40°40'N, 39°40'E, July 1866, *Balansa s.n.* (G, P); Trabzon, Hamsikoy, 40°41'N, 39°28'E, 24 July 1960, *Stainton & Henderson* 6329 (E); Trapezunti, in ditione vici Fol Koei, 40°47'N, 39°16'E, 11 July 1907, *Handel-Mazzetti* 413 (W).

*Discussion*. Like *Geranium crenophyllum*, *G. sintenisii* has constantly long, glandular hairs on stem, petioles, and inflorescence, similar both in

shape and size. However, *G. sintenisii* can be distinguished by its  $\pm$  vertical, turnip-shaped rootstock, without thick fleshy, fasciculate roots, and by its narrow petals. *Geranium chelikii* was described as endemic to the Sivas region of Turkey (the same area as *G. sintenisii*) (Yildiz & Tan 1989). It has been impossible to examine the type or any collection from the type locality of this species. The holotype was apparently sent to E. There, H. Hoy kindly made two exhaustive searches without success. Dr. Askoy (from Istanbul) has contacted to staff at CUFH where the isotype was deposited, also without success. Yildiz & Tan (1989) described *G. chelikii* as bearing "roots slender" rather than "fleshy, fusiform roots" as in *G. asphodeloides*. They also indicated that *G. chelikii* has narrow petals (4-5 mm wide). All these data strongly suggest that *G. chelikii* should be considered as synonym of *G. sintenisii*. *Geranium sintenisii* was recorded from Iran by Köie (1945). Later, Parsa (1952) mentioned the same collection. Schönbeck-Temesy (1970) included this species in "species incertae" in Iran, since she did not find any specimen supporting those records. However, the specimens supporting this record (Köie 339, C, and Köie s.n., C) are *G. rotundifolium*.

*Discussion.* *Geranium dissectum* is the most common and widespread species of the section. It is easily distinguished from all other species of sect. *Dissecta* by deeply divided leaves, short petals, and annual life-span. This species shows cymules shorter than the adjacent leaf, whereas in the three perennial species of the section cymules are longer than the adjacent leaf. *Geranium dissectum* has been frequently confused with *G. columbinum*, which is characterized by seed-ejection with callus fruit (not prong). Additionally, *G. dissectum* has cymules not overtopping the subtending leaf whereas in *G. columbinum* pedicel and peduncle together clearly overtop the subtending leaf. Sometimes it is possible to find depauperate plants of *G. dissectum*, fertile but with the leaves not fully developed. Some such specimens have leaves with undivided segments, and have been named var. *subintegrilobatum*. However, no other character state is associated with this size reduction, which suggests that this form also does not deserve taxonomic recognition.

*Geranium dissectum* has been recorded from Japan (Akiyama 2001; Asai 1975). Unfortunately, it has been impossible to examine the specimens supporting these records. The specimen supporting the record of *G. dissectum* in Peru (Taylor 1993b) is an

unidentified species of sect. *Geranium*. *Geranium dissectum* was also recorded from the Dominican Republic (Moscoso 1943), although no specimen was mentioned. The specimens kept at the National Herbarium (JBSD) as *G. dissectum* are *G. carolinianum*. However, one voucher of *G. dissectum* from Haiti makes reliable its presence from Dominican Republic.

**III. *Geranium* subg. *Tuberosa*** (Boiss.) Aedo, Acta Bot. Malac. 42: 299. 2018. TYPE: *Geranium tuberosum* L. (art. 10.8).

*Fruit* of seed-ejection type. At dispersal, each single seed is launched from mericarp by the explosive recurvature of the awn, while the awn and the mericarp wall remain attached to the columella. *Mericarp* longitudinally compressed at the apex, twisted at its attachment to the awn and without basal prong nor callus.

**IIIa. *Geranium* sect. *Tuberosa*** (Boiss.) Reiche in Engl. & Prantl, Nat. Pflanzenfam. 3(4): 8. 1890. *Geranium* [§] *Tuberosa* Boiss., Fl. Orient. 1: 869. 1867. *Geranium* subsect. *Tuberosa* (Boiss.) Yeo, Bot. J. Linn. Soc. 89: 12. 1984. TYPE: *Geranium tuberosum* L. (art. 10.8).

*Perennials herbs* with tuberculate rootstock.

**259. *Geranium kotschy*** Boiss., Diagn. Pl. Orient. ser. 1, 6: 30. 1846. TYPE LOCALITY: "Geranium Kotschy Boiss. loc. cit. [in pl. Kotsch. Pers.] Febr. 1845... Hab. in glareosis prope nives montis Kuh-Barfi prope Schiraz Kotschy No. 331". TYPE: Iran. Fars, montis Kuh-Barfi prope Schiraz, 29°36'N, 52°32'E, 3 May 1842, *T. Kotschy* 331 (lectotype, designated by Davis 1970: 111, G-BOIS-00365774!; isotypes, BM-000606767!, FI-010373!, GOET-004065 image!, HI!, JE!, K-000074050!,

MO-251006!, OI!, P-00712106!, S05-9884!, UPS!, WI!, WRSL!, WU!, ZI!).

*Perennial herbs*, 8-51 cm tall. *Rootstock* vertical, tuberculate, with tubercles subglobose, 5.4-18.8 mm long, 7.8-22.5 mm wide (ratio tubercle width/tubercle length = 0.6-1.4), superimposed, without non-tuberos separations, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.1-0.5 mm long and, usually, patent, glandular hairs 0.1-1 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite (the first pair usually at stem bifurcation); leaf laminae 1.7-6.6 cm long, 2.2-6.6 cm wide, not peltate, palmatifid to palmatisect [ratio main-sinus length/middle segment length = 0.54-0.95], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5-13, in 1 or more plane, middle segment rhombic, 0.5-4.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.02-0.20], (1)3-12-lobed in distal half [ratio secondary sinus length/middle segment length = 0.18-0.72]; petioles up to 10 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.1-0.7 mm long and, usually, patent, glandular hairs 0.1-0.2 mm long; stipules 2.1-5.7 mm long, 0.7-2.9 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1-3]; peduncles 7-48 mm long, with patent, eglandular hairs 0.1-0.9 mm long and, usually, patent, glandular hairs 0.2-0.7 mm long; bracteoles 0.7-2.1 mm long, 0.3-0.7 mm wide, linear-lanceolate, whorled; pedicels absent or 3-15 mm long, with patent, eglandular hairs 0.2-0.9 mm long and,

usually, patent, glandular hairs 0.1-1 mm long. Flowers actinomorphic. *Sepals* 3.5-6 mm long, 1.5-3.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0)0.2-0.8 mm long [ratio mucro length/sepal length = 0.04-0.18], with  $\pm$  patent, eglandular hairs 0.5-1.7 mm long and usually patent glandular hairs 0.1-0.4 mm long on the abaxial surface, glabrous adaxially. *Petals* 6.8-12.6 mm long, 4.2-8.6 mm wide, erect-patent, emarginate (notch 0.5-2.6 mm deep), without claw, purple, glabrous on both surfaces, rarely hairy on the base of the adaxial surface, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 4.3-6.5 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.9 mm long; anthers 1.3-2 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.6-6.9 mm long, dark purple. *Fruit* 15.6-21.9 mm long, erect, discharge of seed-ejection type; mericarps 2.8-3.8 mm long, 1.4-2 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.1-1.2 mm long and sometimes patent, glandular hairs 0.2-0.6 mm long; rostrum 10.9-15.9 mm long, with a narrowed apex 1.1-3.2 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 0.1-0.4 mm long and, sometimes, patent, glandular hairs 0.3-0.5 mm long; stigmatic remnants 0.9-1.6 mm long, with 5 glabrous lobes. *Seeds* 1.9-2.7 mm long, 1.2-1.8 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with entire margin.

*Pollen*. *Geranium*-type.

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to August.

*Distribution*. This species ranges from western Iran, through Tadzhikistan, Turkmenistan, Uzbekistan to northwestern Afghanistan.

*Habitat*. Grassy or rocky slopes, sometimes on halophytic steppe with *Artemisa*; 500-3300 m.

1. Leaves with 9-13 segments, in more than 1 plane; middle segment with 6-12 lobes; pedicels usually with glandular hairs. **259a. subsp. kotschy**

1. Leaves with 5-7(9) segments, in 1 plane; middle segment with (1)3-7 lobes; pedicels usually without glandular hairs. **259b. subsp. charlesii**

**259a. *Geranium kotschy* Boiss. subsp. kotschy**

*Stem* with patent to retrorse eglandular hairs 0.1-0.4 mm long and, usually, patent glandular hairs 0.1-1 mm long. *Leaf lamina* 1.7-3.9 cm length, 2.2-4.7 cm wide, palmatifid to palmatisect (ratio main-sinus length/middle segment length = 0.75-0.89); segments 9-13, in more than 1 plane, 0.5-1.5 mm at the base, 6-12-lobed in distal half; petioles with patent to retrorse eglandular hairs 0.2-0.7 mm long and, usually, patent glandular hairs 0.1-0.2 mm long. *Peduncles* 7-30 mm length, with patent eglandular hairs 0.2-0.5 mm long and, usually, patent glandular hairs 0.3-0.4 mm long; pedicels 3-13 mm length, with patent eglandular hairs 0.2-0.5 mm long and, usually, patent glandular hairs 0.2-0.4 mm long. *Sepals* 3.5-5.6 mm long, 1.5-2.8 mm wide, with  $\pm$  patent, eglandular hairs 0.6-1.2 mm long and, usually, patent glandular hairs 0.1-0.4 mm long on the abaxial surface, glabrous adaxially. *Petals* 6.8-11.8 mm long, 5-8.6 mm wide, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.5 mm long. Fig. 652 a-j, 653 e.

*Pollen*. *Geranium*-type (Aedo & Estrella 2006: 22; Bortenschlager 1967: 427).

*Chromosome number*. Unknown.

*Phenology*. Flowering specimens from March to August.

*Distribution*. This subspecies ranges from western to central Iran (Figure 654).

*Habitat*. Rocky areas, on limestone or volcanic rocks, usually near melting snow; 1700-2900 m.

**Discussion.** *Geranium kotschyi* is recognized by its vertical rootstock composed of subglobose and super-

imposed tubercles. Tubercles are adjacent, without non-tuberos separations, and diminish in size towards rootstock apex. *G. kotschyi* is also characterized by the absence of the terminal cymule at the first bifurcation of the stem. The remaining species of the sect. *Tuberosa* have a horizontal rootstock with tubercles joined by non-tuberos separations, and usually a terminal cymule at the first bifurcation of the stem. Most plants have the first pair of leaves at stem bifurcation although, rarely, there

are specimens with a pair of opposed leaves below this bifurcation. Basal leaves are absent at flowering time in most herbarium specimens. However, I could check in plants cultivated at Madrid Botanical Garden (*Aedo* 9888) that this feature is variable, and that sometimes basal leaves are present at flowering time. The most important differences between subsp. *kotschyi* and subsp. *charlesii* are found in the leaf shape. The subsp. *kotschyi* has leaves with many segments, which are in more than 1 plane, and the middle segment has many lobes, while subsp. *charlesii* has more simple leaves with few segments in 1 plane and the middle segment with few lobes. In the north of Iran, where both taxa grow, there are intermediate specimens. This strongly supports Davis' proposal (1970) to consider such taxa as subspecies. On the other hand, leaves of subsp. *charlesii* are variable. It usually has deeply divided leaves with narrow segments, but some specimens show broad and not deeply divided segments, and others have segments without lateral lobes. These forms are widespread in all areas of subsp. *charlesii*, and they do not show other distinctive features. The presence of glandular hairs on the inflorescence is useful, as a secondary character, to distinguish subsp. *kotschyi*, although it is not constant. On the contrary, subsp. *charlesii* can occasionally have glandular hairs (Davis 1970).

*Discussion*. *Geranium libanoticum* has a characteristic rootstock with tubercles joined by broad non-tuberous separations. It is also easily separated from *G. tuberosum* by its rostrum with a longer narrowed apex. Both *G. macrostylum* and *G. linearilobum* are partially sympatric with *G. libanoticum*. The first can be differentiated by its glandular hairs and the second by its alternate cauline leaves. This species was described by Schenk (1840) based on material from Lebanese mountains. According to Stafleu &

Cowan (1985: 134), Schenk's herbarium and types at WB and LZ were destroyed. I have been looking for original material in other herbaria where further Schenk's material has been kept, without success. Thus, a neotype from the same area was selected. The record of *G. libanoticum* from Iran by Davis (1970: 111) is based in Stapf 491 (WU). This specimen lacks underground parts and has a pair of opposite leaves below the first bifurcation (as *G. libanoticum* and some specimens of *G. tuberosum*), but the fruit is unequivocally of *G. tuberosum* since it has a short (1.1 mm long) narrowed apex.

not accrescent, nerves 3, mucro 0.23-2.7 mm long [ratio mucro length/sepal length = 0.05-0.42], with  $\pm$  patent, eglandular, hairs 0.3-2.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.2)10.3-13.7(15.2) mm long, 4.9-12.6 mm wide, erect-patent, emarginate (notch 0.9-4.8 mm deep), without claw, purple, glabrous on both surfaces, ciliate on the basal

margin, with hairs 0.2-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.5-7.8 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-2.7 mm long; anthers 1.1-2.4 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.3-6.2 mm long, dark purple. *Fruit* 21.2-29.2 mm long, erect, discharge

of seed-ejection type; mericarps 3.7-4.8 mm long, 1.6-2.1 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  patent, eglandular, hairs 0.3-2.2 mm long; rostrum 15.3-24.5 mm long, with a narrowed apex 1.7-3 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 0.4-1.1 mm long; stigmatic remnants 1.1-2.3 mm long, with 5 glabrous lobes. *Seeds* 2-2.5 mm long, 1.1-1.6 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 657, 658.

*Pollen*. *Geranium*-type (Aedo & Estrella 2006: 25).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to July.

*Distribution*. This species ranges from southern Russia to central Asia (from Caucasus and eastern Turkey to western China and northwestern Afghanistan) (Fig. 659).

*Habitat*. Stony slopes (on granite or limestone), *Artemisia* L. steppes, open forests of *Juniperus* L. or felled; 900-4000 m.

*Representative specimens examined*.

**Discussion.** *Geranium linearilobum* could be confused with *G. malviflorum* since both have cauline alternate leaves and lack glandular hairs on the inflorescence. However the first is easily recognized by its subglobose tubercles, and by its smaller petals and sepals. Davis (1970: 105) recognized two subspecies under *G. linearilobum*. According this author plants with deeply dissected leaf segments into few linear laciniae should be considered as subsp. *linearilobum* (Fig. 658 a, d), while specimens incised or pinnatifid leaf segments belong to subsp. *transversale* (Fig. 658 h, i). Bobrov (1949: 61) accepted these taxa

as species, indicating that *G. transversale* could also be separated from *G. linearilobum* by its longer hairs on the stem. I have found that the type of *G. transversale* shares with the type of *G. linearilobum* leaves with deeply dissected leaf segments. On the other hand, the type of *G. persicum* shows pinnatifid leaf segments, which is more in accordance with the Bobrov's (1949) or Davis' (1970) concept of *G. transversale*. Schönbeck-Temesy (1970: 3) recognized two species in Iran (*G. linearilobum* and *G. persicum*) based on leaf division and staminal filament shape. The variability of leaf shape in *G. linearilobum* is really remarkable and it has not been possible to relate to any geographical area or other characters as hair length or staminal filaments shape. The case showed in Fig. 658 a is very rare and only found in some northern localities, where also leaves with pinnatifid segments are found. Thus these taxa are here considered as synonyms for the reasons above mentioned. The record of *G. linearilobum* from Iraq by Davis (1970: 106) is based in *Al Kas* 18606 and *Rawi* 22220. I was not able to locate these specimens and, unfortunately, Davis (1970) did not specify in what herbaria they were.

**Discussion.** *Geranium macrostylum* is characterized by its rootstock with subglobose tubercles joined by remarkable slender non-tuberos separations, by its inflorescence with glandular hairs, and by its opposite pair of leaves below the first bifurcation. It could be confused with specimens of *G. tuberosum* with opposite leaves below the first bifurcation. However, the longer narrowed apex of the rostrum and the glandular hairs of the inflorescence easily permit one to distinguish both species. *Geranium tuberaria* shares with *G. macrostylum* the presence of glandular hairs on the inflorescence. However, the first has 1-3 alternate cauline leaves while the second has a pair of opposite leaves on the stem. Exceptionally, I have found one spec-

imen of *G. macrostylum* with one additional alternate cauline leaf (*Davis* 41771, K!). Furthermore, leaves of *G. macrostylum* are more deeply divided and with narrower segments than in *G. tuberaria*. Glandular hairs of petioles and pedicels of *G. macrostylum* are shorter than those of *G. tuberaria*, while glandular hairs of sepals and mericarps are longer. *Geranium macrostylum* was recorded in Albania by Qosja (1992: 207), but no specimen has been located to support such record. Davis (1970: 104) recorded this species from Croatia based on *Pichler s.n.* I was not able to locate this specimen and, unfortunately, Davis (1970) did not specify in which herbarium it was.

**263. *Geranium malviflorum* Boiss. & Reut., Pugill. Pl. Afr. Bot. Hispan.: 27. 1852, ["malvaeflorum"].** *Geranium tuberosum* subsp. *malviflorum* (Boiss.) Malag., Subsp. Var. Geogr. 11. 1973. *Geranium tuberosum* var. *debile* Ball, J. Bot. 11: 302. 1873. TYPE LOCALITY: "Hab. In regione superiori Atlantis Majoris. Legimus nondum florentem in convalle Ait Mesan! et in Monte Djebel Tezah! Alt. 2300m-2600m. Specimen unicum mancum florentem invenit cl. G. Maw". TYPE: Morocco. Ait Mesan & Djebel Tezah, 31°13'N, 8°14'W, *G. Maw s.n.* (no original material located).

**Perennial herbs**, 17-64(70) cm tall. **Rootstock** ± horizontal, tuberculate, with tubercles fusiform, 15.3-37.9 mm long, 7.4-13.2 mm wide (ratio tubercle width/tubercle length = 0.3-0.5), with non-tuberos separations 15.3-31.3 mm long, 2-2.8 mm wide, not turnip-shaped, without thickened

roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.2-2 mm long. **Basal leaves** in a ± persistent rosette, cauline leaves alternate (1-2 below the first bifurcation) and upper opposite; leaf laminas (3)3.8-6.9(7.5) cm long, (3.7)4.6-8.6(11.5) cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5-7, in 1 plane, middle segment rhombic, 0.9-3.2 mm wide at the base [ratio segment width at the base/middle segment length = 0.02-0.10], 7-21-lobed in distal half [ratio secondary sinus length/middle segment length = 0.25-0.6]; petioles up to 28 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.2-1.6 mm long; stipules 2.3-4.3 mm long, 1.1-2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. **Inflorescence** a dichasial cyme with monochasial branches; cymules 2-flowered, usually in aggregates at the top of each branch [ratio cymule length/leaf length = 1.2-4.8]; peduncles 21-40(65) mm long, with patent, eglandular hairs 0.2-2.1 mm long; bracteoles 1.8-5.2 mm long, 0.3-1.1 mm wide, lanceolate, whorled; pedicels absent or 7-28 mm long, with patent, eglandular hairs 0.2-1.9 mm long. Flowers actinomorphic. **Sepals** (6.7)7.5-9.1 mm long, 3-5.1 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.7-1.7 mm long [ratio mucro length/sepal length = 0.09-0.25], with ± patent, eglandular, hairs 0.2-2.5 mm long on the abaxial surface, glabrous adaxially. **Petals** (10.3)16.5-19.3(21) mm long, (6)11-16.6 mm wide, erect-patent, emarginate (notch 1.2-3.3 mm deep), without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-1.1 mm long. **Stamens** 10, both whorls bearing anthers; filaments 6-8.6 mm long, lanceolate, purple, pi-

lose on the abaxial surface, ciliate on the proximal quarter, with hairs 0.5-2.7 mm long; anthers 1.7-3 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.2-8.7 mm long, dark purple. *Fruit* 27.3-37.8 mm long, erect, discharge of seed-ejection type; mericarps 3.6-5.4 mm long, 1.3-3 mm wide, without a strand of fibers, compressed at the apex, smooth (rarely with 1-2 transverse veins at the apex), without basal beak, without a basal callus, without a basal prong, black, with  $\pm$  patent, eglandular, hairs 0.2-2.4 mm long; rostrum 19.8-30.7 mm long, with a narrowed apex 2.7-7.3 mm long, twisted distally, with erect-patent, eglandular hairs 0.1-1.8 mm long; stigmatic remnants 1.2-3.3 mm long, with 5 glabrous lobes. *Seeds* 2-2.8 mm long, 1.7-1.8 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 663, 664.

**Pollen.** *Geranium*-type (Aedo & Estrella 2006: 25; Bortenschlager 1967: 427; Velasco 1992b: 57).

**Chromosome number.**  $2n = c. 56$ .

**Phenology.** Collected in flower from March to September.

**Distribution.** This species ranges from southern Portugal and Spain to northwestern Africa (Morocco and Algeria) (Fig. 665).

**Habitat.** Fields, grassy or rocky places in open areas of *Quercus* L. and *Cedrus* Mill. forests (or limestone or volcanic rocks); 200-2500 m.

**Representative specimens examined. ALGERIA.** AIN DEFLA: Aurasii montes, circa Sgag, 36°17'N, 1°44'E, 17 June 1938, *Maire s.n.* (MPU); Milianah, 36°18'N, 2°9'E, *Pomel s.n.* (MPU). **Discussion.** *Geranium malviflorum* is the most robust species of the section. It also has longer petals and sepals, and fusiform tubercles unique in the group. *G. malviflorum* shares with *G. tuberaria* alternate leaves on the stem, although it could easily be differentiated by the absence of glandular hairs. I have found little variability in this species. The most noticeable was one specimen with two seeds per mericarp, and some other with subopposite cauline leaves. According to Davis (1970: 104), *G. malviflorum* is also present in Tunisia, although no specimen is mentioned. I was not able to locate any specimen from this country. Both Bonnet & Barratte's catalogue (1896: 82) and Pottier's flora (1979: 429) only recorded one species of sect. *Tuberosa*: *G. tuberosum*.

**264. *Geranium tuberaria* Jacquem.** ex Cambess. in Jacquem., Voy. Inde 4: 33, tab. 37. 1844. TYPE LOCALITY: "*Geranium tuberaria*. Jacquem. Mss. ... Frequens in nemoribus prope castellum vulgo Ouri in regno Cachemir. Floret Maio". TYPE: India. regno Cachemir, V. Jacquemont s.n. (lectotype, designated by Aedo & Estrella 2006: 44, P-00757944!; isolectotype, MPU!).

*Perennial herbs*, 26-50 cm tall. *Rootstock* ± horizontal, tuberculate, with tubercles subglobose, 10.1-22.2 mm long, 8.3-19.1 mm wide (ratio tubercle width/tubercle length = 0.6-1.1), with non-tuberos separations 3.7-49.2 mm long, 1.2-3 mm wide, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.5-1.7 mm long and patent, glandular hairs 0.2-0.6 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves alternate (1-3 below the first bifurcation) and upper opposite; leaf laminas 1.9-5.5 cm long, 3.4-7.1 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.60-0.80], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, with appressed, eglandular and sometimes glandular hairs on both surfaces; segments 5, in 1 plane, middle segment rhombic, 1.6-5.3 mm wide at the base [ratio segment width at the base/middle segment length = 0.06-0.19], 10-19-lobed in distal half [ratio secondary sinus length/middle segment length = 0.27-0.35]; petioles up to 22 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.5-1.1 mm long and patent, glandular hairs 0.2-0.4 mm long; stipules 2.4-5.3 mm long, 0.5-1.4 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.3-

2.4]; peduncles 12-104 mm long, with patent, eglandular hairs 0.4-1 mm long and patent, glandular hairs 0.3-0.6 mm long; bracteoles 1.6-3.5 mm long, 0.3-0.7 mm wide, linear-lanceolate, whorled; pedicels 9-35 mm long, with patent, eglandular hairs 0.6-1.1 mm long and patent, glandular hairs 0.3-0.8 mm long. Flowers actinomor-

phic. *Sepals* 6.1-9.5 mm long, 2.2-4.2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.6-1.2 mm long [ratio mucro length/sepal length = 0.09-0.19], with  $\pm$  patent, eglandular hairs 1.1-2.5 mm long and usually patent glandular hairs 0.3-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 11.7-

21.4 mm long, 8.3-14.8 mm wide, erect-patent, emarginate (notch 0.8-2 mm deep), without claw, purple, glabrous on both surfaces, ciliate on the basal margin, rarely hairy around all margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.4-8.5 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 1.4-2.8 mm long; anthers 1.3-2.4 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 4.5-8.5 mm long, dark purple. *Fruit* 17.4-32.6 mm long, erect, discharge of seed-ejection type; mericarps 2.8-4.9 mm long, 2-2.4 mm wide, without a strand of fibers, compressed at the apex, smooth (rarely with 2-3 transverse veins at the apex), without basal beak, without a basal callos, without a basal prong, brown, with  $\pm$  patent, eglandular hairs 0.4-1 mm long and patent, glandular hairs 0.3-0.4 mm long; rostrum 12.2-25.9 mm long, with a narrowed apex 1.9-3.1 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 0.1-0.6 mm long and patent, glandular hairs 0.3-0.6 mm long; stigmatic remnants 1.1-1.8 mm long, with 5 glabrous lobes. *Seeds* 2.4-3.2 mm long, 1.2-2.1 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 666.

*Pollen*. *Geranium*-type (Aedo & Estrella 2006: 22).

J.L. Castillo/05

Fig. 666. *Geranium tuberaria*. a. Habit. b. Leaf. c. Indumentum of the pedicel. d. Flower without petals and sepals. e. Sepal. f. Petal. g. Staminal filament. h. Fruit. i. Mericarp. j. Seed. (Based on: a-g, Ellis s.n., Aug. 1880, K; h-j, Hooker & Thompson s.n., s.d., C).

Fig. 667. Distribution of *Geranium tuberaria*.

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from April to August.

*Distribution.* This species ranges through northwestern India (Jammu and Kashmir and Himachal Pradesh) (Fig. 667).

*Habitat.* Grassy hill slopes or fields; 2000-3600 m.

*Additional specimens examined.* **India.** [without locality], 11 May 1881 (CAL); hab Himal. Bor. Occ., *Hooker & Thomson s.n.* (BM, C, FI, G, K, L, LD, NY, P, S, UPS, W, Z); HIMACHAL PRADESH: Chenas valley, Chamba, 32°33'N, 76°7'E, Aug. 1880, *Ellis s.n.* (K); Pangl, below Sach Pass, between pass and Dunai Sarai, 33°0'N, 76°25'E, 8 June 1981, *Sayers 3700* (BM); Chenas valley, Kilar, 33°5'N, 76°25'E, 9 June 1979, *Stainton 8109* (BM); JAMMU-KASHMIR: Wardwan valley, 33°45'N, 75°38'E, 6 May 1976, *Stainton 7539* (BM); Athwatu, Bandapur, 34°25'N, 74°39'E, 25 Apr. 1940, *Ludlow & Sherriff 7582* (BM).

*Discussion.* This species endemic to NW India was not included in Davis' (1970) revision of sect. *Tuberosa*. However, it has a "seed-ejection-type" fruit, with no structure for retaining the seed in the pre-explosive interval, and is twisted at its attachment to the awn, because it unequivocally belongs to this section (Yeo, 1984). Its differences with *G. macrostylum* and *G. malviflorum* have been mentioned under these species. It can be differentiated from *G. linearilobum*, which also has alternate cauline leaves, by the presence of glandular hairs on the inflorescence. *G. tuberaria* is a species with little variability. Some specimens have subopposite leaves. The mericarp is usually smooth but occasionally has 2-3 transversal veins at the apex. Petals are usually ciliate on the basal margin, although rarely they have hairs around all.

*Perennial herbs*, 16-48 cm tall. *Rootstock* ± horizontal, tuberculate, with tubercles subglobose, 6.6-23.7 mm long, 6.7-19.9 mm wide (ratio tubercle width/tubercle length = 0.6-1.2), with non-tuberous separations 5.1-36.6 mm long, 0.6-2.2(2.7) mm wide, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons ab-

sent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-0.6 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite (the first pair usually at stem bifurcation; sometimes 1 pair below the first bifurcation); leaf laminae 2-9.7 cm long, 2.8-12.4 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5-9, in 1 plane, middle segment rhombic (sometimes lanceolate), 0.5-1.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.01-0.03], 7-35-lobed in distal half [ratio secondary sinus length/middle segment length = 0.04-0.59]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.1-0.5 mm long; stipules 1.9-3.5 mm long, 0.7-2.4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with usually monochasial branches; cymules 2-flowered, usually in aggregates at the top of each branch [ratio cymule length/leaf length = 0.8-2.3]; peduncles 19-54 mm long, with patent, eglandular hairs 0.1-0.6 mm long; bracteoles 0.7-3 mm long, 0.3-1 mm wide, linear-lanceolate, whorled; pedicels absent or 7.4-22.6 mm long, with patent, eglandular hairs 0.2-1.1 mm long. Flowers actinomorphic. *Sepals* 4.2-6.3(6.6) mm long, 2.2-3.9 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.3-1.4 mm long [ratio mucro length/sepal length = 0.07-0.31], with ± patent, eglandular hairs 0.5-2 mm long on the abaxial surface, glabrous adaxially. *Petals* 6.9-12(17.1) mm long, 4.2-14.3 mm wide, erect-patent, emarginate (notch 0.9-4.4 mm deep), without claw, purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.5-1 mm long. *Stamens* 10, both whorls bearing anthers; fil-

aments 2.5-5.4 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-1.5 mm long; anthers 0.8-2.3 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.7-4.9 mm long, dark purple. *Fruit* 13.3-15.8 mm long, erect, discharge of seed-ejection type; mericarps 3-4.1 mm long, 1.4-1.9 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with ± patent, eglandular hairs 0.2-1.6 mm long; rostrum 8.6-16.2 mm long, with a narrowed apex 0.2-0.5(2.1) mm long, twisted distally, with erect-patent, eglandular hairs 0.3-1 mm long; stigmatic remnants 0.9-1.6 mm long, with 5 glabrous lobes. *Seeds* 2-2.9 mm long, 1.3-2 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 668-670.

*Pollen*. *Geranium*-type (Aedo & Estrella 2006: 22).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from February to June.

*Distribution*. This species ranges from southern Europe (from France to southern Russia) and northern Africa (from Algeria to Libya) to western Asia (from Turkey to Iran) (Fig. 671).

*Habitat*. Open areas of *Quercus* L., *Abies* Mill., and *Pinus* L. forests, scrubland with *Crataegus* L., *Cistus* L., and *Pistacia* L., and *Artemisia* L. steppes (on limestone or basaltic rocks) or fields; 0-2800 m.

*Representative specimens examined*.

Fig. 670. *Geranium tuberosum* (Based on: Muñoz Garmendia & al. 4534, MA).

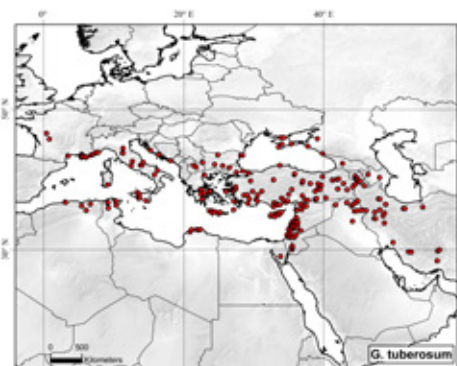

Fig. 671. Distribution of *Geranium tuberosum*.

**Discussion.** *Geranium tuberosum* is a species that extends from France to Iran, which exhibits significant variability. As Davis (1970) already mentioned, its narrowed apex of the rostrum is shorter than any other taxa in the group. Other differences with different species of the section have been previously mentioned. Davis (1970: 106) recognized two subspecies under *G. tuberosum*. According to this author, plants with deeply divided leaf segments and lacking a pair of leaves below the first bifurcation should be considered as subsp. *tuberosum*, while specimens incised or dentate leaf segments and with a pair of leaves below the first bifurcation belong to subsp. *linearifolium*. To Davis (1970) subsp. *tuberosum* occurs from France to west Iran, and sub-

sp. *linearifolium* grow from central Turkey to central Iran. This opinion is also shared by Schönbeck-Temesy (1970: 3), who prefers the specific rank to both taxa (*G. tuberosum* and *G. stepporum*). I have found plants

with a pair of cauline leaves scattered through the area of the species. This character is not related with leaf division. Additionally, variation in leaf division appears to be continuous. As Davis (1970: 108) stated, *G. tuberosum* is exceptionally variable in Turkey and related areas. In these places specimens with all possible combinations of the previously mentioned characters (sometimes in the same collection: i.e., *Bornmüller 13945*, BM!, LD!, Z!) are common. Thus these taxa are here considered as synonyms for the reasons above mentioned. Two collections from Turkey (*Aznavour 491*, G!) and *Davis 21710* (BM!, E!, K!) are exceptional in having glandular hairs on the inflorescence. In the first the fruit has a rostrum with a short narrowed apex, such as *G. tuberosum*. The second has fruits that are not well developed but is otherwise typical of *G. tuberosum*. Some specimens show a tendency to develop an unequal ramification, and in rare cases to have one alternate cauline leaf. These exceptions have been observed in gathering of normal plants. In this species base of stem and petioles are very thin, which could facilitate their breakage and avoids tubercle predation. Davis (1970: 107) recorded *G. tuberosum* from Romania based on *Borza & Buia 2000* (9 May 1939, C!, O!, W!, Z!). This specimen was collected in "Caliacra, Dobroega, pr. Ghiaur-Suiuciu", a locality now belonging to Bulgaria. Șervănescu (1959: 119) did not mention any species of sect. *Tuberosa* as belonging to Romania flora. I was not able to locate any specimen of *G. tuberosum* from Albania, although it was recorded there by Qosja (1992: 207). This species was also recorded from Corse (Briquet & Litardière 1936: 14) but it has not been collected again (Gamisans & Jeanmonod, 1993: 182).

According to Van Loon (1984b: 269), the report of chromosome number  $2n = 28$  for *G. tuberosum* (Van Loon & Oudemans 1982: 343) is based on a wrongly identified specimen of *G. macrostylum*.

### IIIb. *Geranium* sect. *Lanuginosa*

Rouy in Rouy & Foucaud, Fl. France 4: 87. 1897. TYPE: *Geranium lanuginosum* Lam. (art. 10.8).

*Geranium* subsect. *Mediterranea* R. Knuth in Engl., Pflanzenr. 53: 107. 1912. TYPE: *Geranium platypetalum* Fisch. & C.A. Mey. (designated by Yeo 1984: 12).

*Geranium* sect. *Bohemica* Tzvelev in Nov. Syst. Pl. Vasc. 29: 95. 1993. TYPE: *Geranium bohemicum* L. (art. 10.8).

*Annual or perennial herbs* with a  $\pm$  horizontal rootstock, not tuberculate.

**266. *Geranium bohemicum* L., Cent. Pl. II: 25. 1756. *Geranium caeruleum* Moench, Methodus: 284. 1794, nom. illeg. TYPE LOCALITY:** "Habitat in Bohemia? Miller". TYPE: Czech Republic. Bohemia, *Ph. Miller s.n.* (lectotype, designated by Novoselova 1998: 150, LINN 858.69 image!).

*Annual herbs*, 20-73 cm tall. *Stem* erect, leafy, with patent, eglandular hairs 1.2-2.9 mm long and patent, glandular hairs 0.5-0.8 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves alternate (1-3) and upper opposite; leaf laminae 2.2-6.8 cm long, 3.1-8.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.47-0.57], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular (and sometimes glandular) hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 4-11.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.29], 7-27-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.21]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinete, eglandular hairs 0.1-0.3 mm long, patent eglandular hairs 1.4-2.7 mm long, and patent, glandular hairs 0.4-1.2 mm long; stipules 5.8-11.5 mm

long, 0.7-2.4 mm wide, lanceolate, free, papery, brown, with eglandular and glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1-2.9]; peduncles 11-68 mm long, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 2-3 mm long and patent, glandular hairs 0.3-0.6 mm long; bracteoles 1.4-5.5 mm long, 0.3-0.8 mm wide, linear-lanceolate, whorled; pedicels 4-30 mm long, with uncinete eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 1.6-2.6 mm long and patent, glandular hairs 0.3-0.6 mm long. Flowers actinomorphic. *Sepals* 5.2-12.4 mm long, 2.2-6.9 mm wide, lanceolate, smooth, accrescent, nerves 5, mucro 1.1-3.4 mm long [ratio mucro length/sepal length = 0.15-0.45], with patent eglandular hairs 1.8-2.6 mm long and patent glandular hairs 0.4-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (5.5)5.8-7.7(9.4) mm long, 3.5-6.9 mm wide, erect-patent, emarginate (notch 0.6-1.5 mm deep), without claw, blue, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal and apical margin, with hairs 0.3-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.8-4.7 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.4-1 mm long; anthers 0.7-1.3 mm long, yellow. *Nectaries* 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3-4 mm long, purple. *Fruit* 24-29.9 mm long, erect, discharge of seed-ejection type; mericarps 4.9-6.1 mm long, 1.7-2.9 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, black, with  $\pm$  patent eglandular hairs 1.2-2.4 mm long and scattered glandular hairs 0.4-0.8 mm long at the apex; rostrum 17.3-23.2 mm long, without a narrowed

apex, twisted distally, with patent, eglandular 0.5-1.7 mm long and patent, glandular hairs 0.3-0.7 mm long; stigmatic remnants 0.8-2.2 mm long, with 5 hairy lobes. *Seeds* 2.8-4.4 mm long, 1.5-2 mm wide, finely reticulate, mottled, brown, glabrous. Cotyledons with a notch on each side margin. Figs. 672 a-j, 673.

*Pollen*. *Geranium*-type (Aedo & al. 2007: 99; Stafford & Blackmore 1991: 66; Velasco 1992b: 57).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from April to November.

*Distribution*. This species ranges from southern Finland to Spain and Greece, Caucasus and northern Turkey (Fig. 675).

*Habitat*. Open areas of *Quercus* L., *Fagus* L., *Abies* Mill., *Picea* A. Dietr. and *Pinus* L. forests, on limestone or acid rocks, usually on recently burned sites; 0-1800 m.

**Discussion.** *Geranium bohemicum* is recognized by its cotyledons, which are notched on each side, its brownish seeds with clearer areas, its pet-

als with ciliae on the apical margin, and its hairy nectaries. It has usually been considered closely related to *G. lanuginosum*. However, the latter species has entire cotyledons, uniformly reddish seeds, petals without ciliae at the apex, and glabrous nectaries. Additionally, in *G. bohemicum* the leaves are not as deeply divided (the ratios main-sinus length/middle segment length, and secondary sinus length/middle segment length are lower), and the eglandular hairs of peduncles and pedicels are longer than in *G. lanuginosum*. *Geranium bohemicum* shares with *G. lanuginosum* some character states not present in the remaining species of sect. *Lanuginosa*. Both are annuals, with accrescent sepals, inflorescence in dichasial cyme with monochasial branches, and blackish mericarps. Additionally, they have shorter petals, staminal filaments, anthers, and gymnoecia than the perennials species of the section. The fruits are also shorter, without narrowed apices in the rostrum, and the abaxial side of the stigmatic remnants is hairy instead of glabrous, as in the perennial species.

According to Dahlgren (1952) and Milberg (1994), the seeds remain viable over long time periods (at least 129 years). If not subjected to heat, the seeds do not easily germinate. This species often appears suddenly after forest fires, as can be confirmed from many herbarium labels. Thus, *G. bohemicum* seems to be well adapted to occasional natural forest fires that may occur after long time lags. This could partially explain its scattered distribution and temporal disappearance in some localities.

**267. *Geranium lanuginosum* Lam.,** Encycl. 2: 655. 1788. *Geranium bohemicum* subsp. *lanuginosum* (Lam.) O. Bolòs & Vigo, Butll. Inst. Catalana Hist. Nat. 38: 81. 1974. TYPE LOCALITY: "...celle-ci que M. l'Abbé Poirét a trouvée en Afrique, qu'il nous a commu-

niquée... Cette plante croît dans la Numidie. (v.s.)" [according to Briquet (1936: 9) from la Calle]. TYPE: Algeria. Numidie, *J.L. Poirét s.n.* (lectotype, designated by Aedo & al. 2007: 107, P-00389440!).

TYPE LOCALITY: "Hab. Sueciae ad Ekvik prope Segersgårde paroeciae Lofta Smolandiae, ubi unicum inventum est specimen, quod in generationibus conpluris prolem stabilem produxit". TYPE: Sweden. Ad Ekvik prope Segersgårde paroeciae Lofta Smolandiae, 57°50'N 16°32'E, *E.G. Almquist s.n.* (lectotype, designated by Aedo & al. 2007: 107, Svensk Bot. Tidskr. 10: 2 fig. 1A. 1916).

**Annual herbs**, 29-61 cm tall. **Stem** erect, leafy, with patent, eglandular hairs 1.2-2.1 mm long and patent, glandular hairs 0.2-0.9 mm long. **Basal leaves** in a ± persistent rosette, cauline leaves alternate (1-3) and upper opposite; leaf laminae 3.2-8.6 cm long, 3.8-10.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.58-0.68], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular (and sometimes glandular) hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 3.3-8.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.19], 10-18-lobed in distal half [ratio secondary sinus length/middle segment length = 0.21-0.36]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinete, eglan-

Fig. 674. *Geranium lanuginosum* (Based on: Aedo 24060, MA).

dular hairs 0.1-0.3 mm long, patent, eglandular hairs 1.1-2.2 mm long and patent, glandular hairs 0.3-0.7 mm long; stipules 5.3-13.9 mm long, 1-2.1 mm wide, linear-lanceolate (sometimes with a short bifid apex), free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.3-3.4]; peduncles 4-59 mm long, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.3-1.9 mm long and patent, glandular hairs 0.4-0.6 mm long; bracteoles 1.8-4.7 mm long, 0.4-0.9 mm wide, linear-lanceolate, whorled; pedicels 3-24 mm long, with uncinete eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.2-1.6 mm long and patent glandular hairs 0.4-0.7 mm long. Flowers actinomorphic. *Sepals* 5-9.9 mm long, 1.9-5.4 mm wide, lanceolate, smooth, accrescent, nerves 5, mucro 0.9-2.5 mm long [ratio mucro length/sepal length = 0.16-0.31], with patent eglandular hairs 0.9-3.3 mm long and patent glandular hairs 0.6-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (5.4)6.3-6.9(8.3) mm long, 3.1-6.1 mm wide, erect-patent, emarginate (notch 0.4-1.2 mm deep), without claw, blue, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.1-4 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on all of its length, with hairs 0.5-1.3 mm long; anthers 0.6-1.1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.1-4 mm long, purple. *Fruit* 18-29.5 mm long, erect, discharge of seed-ejection type; mericarps 4.1-5.5 mm long, 1.5-2.6 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, black, with  $\pm$  patent eglandular hairs 1.5-2.8 mm long and scattered glandular hairs 0.4-0.9 mm long at the

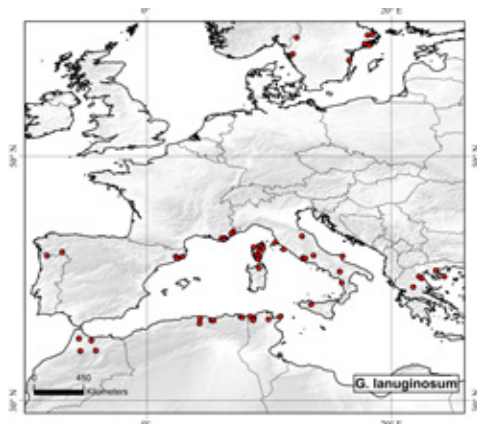

Fig. 676. Distribution of *Geranium lanuginosum*.

apex; rostrum 12.1-20.5 mm long, without a narrowed apex, twisted distally, with patent, eglandular 0.2-0.9 mm long and patent, glandular hairs 0.5-0.8 mm long; stigmatic remnants 1-1.8 mm long, with 5 hairy lobes. *Seeds* 2.5-3.4 mm long, 1.3-2.1 mm wide, reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 672 k-n, 674.

**Pollen.** *Geranium*-type (Aedo & al. 2007: 99; Stafford & Blackmore 1991: 68).

**Chromosome number.**  $2n = 42, 48$ .

**Phenology.** Collected in flower from March to September.

**Distribution.** This species ranges from southern Europe (from Portugal to Greece) to northwestern Africa (from Morocco to Tunisia) and it is introduced in Sweden (Fig. 676).

**Habitat.** Open areas of *Castanea* Mill., *Corylus* L. or *Quercus* L. forests, on limestone or acid rocks, usually on recently burned sites; 0-1600 m.

**Representative specimens examined.**

**Discussion.** Differences between *G. lanuginosum* and *G. bohemicum* are addressed in the discussion under the latter species. It is interesting to note that glandular hairs on the mericarp are restricted to the apex as well as in *G. bohemicum*, *G. gracile*, and *G. renardii*. *Geranium perrey-mondii* was validly published (Roux 1880) by reference to the Godron's (1847) description of *G. bohemicum*. According to the Shenzhen Code (art. 7.8), the type should be selected among the specimens mentioned by Godron (1847). Unfortunately, not one of those specimens was traced. Thus, a specimen mentioned by Roux (1880) was selected as type, which must then be considered to be a neotype (Aedo & al. 2007: 107). Since no original material of *G. bohemicum* subsp. *depraehensum* was located, this name was typified on an illustration. It should be indicated that specimens collected later by Almqvist (labeled by himself as "depraehensum") are unequivocally *G. lanuginosum*. According to Dahlgren (1952), *G. lanuginosum* seeds are similar to those of *G. bohemicum* in germination features.

The ranges of both species overlap only in the Iberian Peninsula and southern France, where sympatric populations are very rare. I have been able to verify the abundance of the two species in the locality discovered by P. Bariego [Spain, Zamora, Porto, *Aedo & Bariego 24061* (MA)]. They were in flower at the same time and in the same plot, but no intermediate specimens were found.

**268. *Geranium gracile*** Ledeb. in Nordm., Bull. Sci. Acad. Imp. Sci. Saint-Pétersbourg 2(20): 314. 1837. TYPE LOCALITY: "Hab. In Awhasien auf dem Gebirge Hirtscha 3000 Fuss hoch". TYPE: Georgia. **Discussion.** *Geranium gracile* shows some features not present in other perennial species of sect. *Lanuginosa*. This taxon usually has more than one pair of opposite leaves on the stem, the inflorescence is a monochasial cyme, and the cymules are solitary (not in aggregates at the top of the branches). Additionally, its petals are the narrowest of the group. Among the perennial species, *G. gracile* shares with *G. ibericum*, *G. peloponnesiacum*, *G. platypetalum*, and *G. renardii* the presence of glandular hairs on the inflorescence. Superficially, *G. gracile* is similar to *G. nodosum* in flower appearance and particularly in leaf form. Leaves of both species have marked ovate segments, with the wider part near the base, and with less deeply divided secondary divisions. Yeo (2002a) suggested that this similarity could be related with the analogous forestry habitat of both species. Knuth (1912) includes *G. gracile* and *G. nodosum* in sect. *Striata* R. Knuth, overlooking the fact that fruit structure unequivocally approaches *G. gracile* of sect. *Lanuginosa*.

**269. *Geranium renardii*** Trautv. in Trautv., Regel, Maxim. & C. Winkl., Decas Pl. Nov.: 5. 1882. TYPE LOCALITY: "In Ossetia, ad. fl. Didi Liachva, in alpe Brutsabseli, 16 Jul. 1881 legerunt A. H. et V. F. Brotherus". TYPE: Georgia. Ossetia, in alpe Brutsabseli, ad fl. Didi Liachva, 42°24'N, 44°15'E, 16 July 1881, *A.H. Brotherus & V.F. Brotherus 215* (lectotype, designated by Knuth 1912: 110, LE!; isolectotype, BM-000606718!, G-003657775!, H-1368908!).

*Perennial herbs*, 14-35 cm tall. *Rootstock* 7.6-14.2 mm in diameter,

± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.3-0.8 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminae 2.3-7.2 cm long, 2.6-8.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.26-0.59], polygonal in outline, base cordate, not coriaceous, reticulate, with nerves projected on the abaxial surface, sunken adaxially, pilose above and sericeous beneath, with ± patent eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment ± obtriangular, 5.6-23 mm wide at the base [ratio segment width at the base/middle segment length = 0.29-0.49], (12)16-21(29)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.07-0.20]; petioles up to 22 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.3-0.6 mm long; stipules 6.2-11.1 mm long, 1.3-4.2 mm wide, lanceolate, free, papery, brown, with eglandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1.3-3.9]; peduncles 5-62 mm long, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.4-1.2 mm long, and rarely patent, glandular hairs 0.2-0.4 mm long; bracteoles (3.4)4.7-6.1(10.4) mm long, 0.7-1.9 mm wide, linear-lanceolate, whorled; pedicels absent or 6-23 mm long, with uncinete eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.6-1.5 mm long and, usually, patent glandular hairs 0.2-0.9 mm long. Flowers actinomorphic. *Sepals* 7.4-10.9 mm long, 3.2-5.1 mm wide, lanceolate, smooth, not accrescent, nerves 5-7, mucro 0.6-1.4 mm long [ratio mucro length/sepal length = 0.05-0.15], with ± patent eglandular hairs (0.3)1-3.4 mm long and, usually, patent, glandular hairs 0.3-0.9 mm long on the

abaxial surface, glabrous adaxially. *Petals* (15.1)16.8-20.3(23) mm long, 10-14.8 mm wide, patent, emarginate (notch 1-5.5 mm deep), without claw, white with violet veins, glabrous on the adaxial surface, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.3-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 7.2-12.9 mm long, lanceolate, white with deep purple apex, pilose on the abaxial surface, ciliate on the proximal half, with hairs 1-2.8 mm long; anthers 1.9-3.3 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5.8-9.9 mm long, pink. *Fruit* 23-34.5 mm long, erect, discharge of seed-ejection type; mericarps 5-6.6 mm long, 2-2.8 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with ± patent eglandular hairs 0.8-1.8 mm long and, sometimes, scattered glandular hairs 0.4-0.8 mm long at the apex; rostrum 15.9-26 mm long, with a narrowed apex 3.4-5.2 mm long, twisted distally, with ± patent eglandular hairs 0.5-2.4 mm long and, rarely, patent glandular hairs 0.3-0.7 mm long; stigmatic remnants 1.4-3.1 mm long, with 5 glabrous lobes. *Seeds* 3-3.6 mm long, 1.4-2.1 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 680, 681.

*Pollen.* *Geranium*-type (Aedo & al. 2007: 99).

*Chromosome number.* Unknown.

*Phenology.* Collected in flower from May to August.

*Distribution.* This species ranges through western and central Caucasus (Fig. 682).

*Habitat.* Alpine meadows or scrubland with *Rhododendron* L. and *Juniperus* L.; 2000-3300 m.

**Discussion.** The leaves of this species are distinctive, permitting *G. renardii* to be distinguished even in vegetative state. They have a noticeable reticulate nervation projected on the abaxial surface, and sunken adaxially. The leaf lamina is green but pilose on the abaxial surface (mainly on the nerves), and densely covered with a patent, sericeous indumentum beneath which is both on the nerves and the sunken surface between them. The inflorescence is dichotomously branched with a long pedunculate cymule at the main fork. Terminal cymules are usually in aggregates (sometimes with short or without pedicels) at the top of the branches, resembling umbels. This type of inflorescence is shared with the following

species of sect. *Lanuginosa* (*G. ibericum*, *G. platypetalum*, *G. peloponnesiacum*, *G. libani*, *G. gymnocaulon*, and *G. kurdicum*). The indumentum shows some variability in *G. renardii*. On the inflorescence, glandular hairs are usually restricted to pedicels and sepals, and in a few cases can be observed on peduncles. However, in some specimens only eglandular hairs are present. Petals are hairy on the base of abaxial surface, and on the basal margin, but in exceptional cases, they can be present all the entire margin, from the base to the notch.

**Discussion.** *Geranium ibericum* has a characteristic dense indumentum of long, soft, patent eglandular hairs along the inflorescence. However, the presence and distribution of glandular hairs is variable. In some specimens, these hairs are lacking, while in others they are abundant and intermixed with eglandular ones, together with some intermediate forms. Collections with both extremes (*Davis & Hedge* 32285, *Sintenis* 7053, *Woronow & Schelkownikow*, *Herb. Fl. Cauc.* 32) are not rare. *Geranium montanum* was accepted by Bobrov (1949), who also recognized *G. ibericum*. They were distinguished by the presence of glandular hairs on the inflorescence in the first and the absence in the second. Davis (1967) treated Turkish specimens with glandular hairs as *G. ibericum* subsp. *jubatum*. Both taxa are here considered as synonyms for the reasons above mentioned. *Geranium ibericum* shares with *G. platypetalum* a general appearance as well as the indumentum of long, soft, patent eglandular hairs along the inflorescence. However, in *G. platypetalum* glandular hairs are always present, even on the basal part of the stem. *Geranium ibericum* has leaves with rhombic middle segments, while *G. platypetalum* has obtriangular segments. Additionally, *G. platypetalum* has longer bracteoles, longer sepal mucros, and shorter petals than *G. ibericum*.

The first effective lectotypification of *G. ibericum* appears to be that of Novoselova (1998), who designated the Cavanilles plate as the "type". The proposal by Novoselova is technically correct, but it could be improved by designating an epitype for a more precise application of the name. However, during the review of the proposal to conserve the name *G. ibericum* (Aedo 2005), J. McNeill and J.H. Wiersema kindly suggested a simpler solution, and thus I proposed a conserved type. According to Van Loon

(1984b: 268) the chromosome count of  $2n = 56$  for this species (Gauger 1937: 529) should be confirmed.

*Geranium ibericum* is an endemic species from Caucasus that is widely used in gardens and occasional or naturalized in Canada, Great Britain, and U.S.A.

*Perennial herbs*, 25-57 cm tall. *Rootstock* 6.2-13.8 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.2-4.9 mm long and, usually, patent, glandular hairs 0.6-1.8 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas 3.6-11.2 cm long, 4.6-12.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.43-0.58], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular (and sometimes

glandular) hairs on both surfaces; segments 5(7), in 1 plane, middle segment  $\pm$  obtriangular, 9.6-27.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.28-0.49], (9)17-25(29)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.15-0.26]; petioles up to 30 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 2.2-4.7 mm long and, usually, patent, glandular hairs 0.3-1.8 mm long; stipules 6.5-13 mm long, 2.2-4.6 mm wide, broadly lanceolate, free, papery, brown, with eglandular and glandular hairs on both surfaces and on the margin. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1.5-3.4]; peduncles 22-134 mm long, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs (1.9)2.5-3.6(4.8) mm long and patent, glandular hairs 0.7-1.5 mm long; bracteoles (8.4)9.6-14.1(18.8) mm long, 0.7-1.6 mm wide, linear-lanceolate, whorled; pedicels absent or 8-23 mm long, with uncinete eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 2.2-4.5 mm long and patent, glandular hairs 0.9-2 mm long. Flowers actinomorphic. *Sepals* 8.2-12.5 mm long, 3-5.4 mm wide, lanceolate, smooth, not accrescent, nerves 5-7, mucro 2-5.5 mm long [ratio mucro length/sepal length = 0.20-0.51], with patent eglandular hairs 0.2-5.4 mm long and patent glandular hairs 0.5-2.6 mm long on the abaxial surface, glabrous adaxially. *Petals* (14.7)16.7-18.7(20.9) mm long, 10.5-18.1 mm wide, patent, emarginate (notch 0.5-1.9 mm deep), without claw, blue, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 8.4-12.5 mm long, lanceolate, dark purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 2.5-4.1 mm long; anthers 2.7-3.4 mm long, blue black. Nectaries

5, hemispheric, glabrous. *Gynoecium* 7.8-11.2 mm long, dark purple. *Fruit* 31.7-38.8 mm long, erect, discharge of seed-ejection type; mericarps 4-5.5 mm long, 2-2.9 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  patent eglandu-

lar hairs 1-2.5 mm long and patent, glandular hairs 0.40-1 mm long; rostrum 22.3-30.9 mm long, with a narrowed apex 3.8-5.9 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 2.3-3.8 mm long and patent, glandular hairs 0.7-1 mm long; stigmatic remnants 1.6-3.8 mm long, with 5 glabrous lobes. *Seeds* 2.8-3.5

mm long, 1.8-2.4 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 686, 687.

*Pollen.* *Geranium*-type (Aedo & al. 2007: 99; Bortenschlager 1967: 427).

*Chromosome number.*  $2n = 28, 42$ .

*Phenology.* Collected in flower from May to August.

*Distribution.* This species ranges from northeast Turkey to Caucasus and northern Iran (Fig. 688).

*Habitat.* Edge of *Betula* L., *Picea* A. Dietr. and *Abies* Mill. forests, or alpine meadows, on igneous rocks; 1200-2700 m.

**Discussion.** *Geranium platypetalum* can be confused with glandular forms of *G. ibericum* (see discussion of *G. ibericum*, above). Basal leaves should

Fig. 688. Distribution of *Geranium platypetalum*.

be used to discriminate these species, because they show more clearly obtriangular segments than cauline ones. Hohenacker (1833) published "*G. platypetalum* Fisch. & Mey. in literis" based on a specimen collected in "montis Sarial", but with no description. This species was republished two years later by Fischer & Meyer (1835) with a full description, but without any reference to Hohenacker's publication. They indicated a general area, "Hab. in montibus et subalpinis Somchetiae, Iberiae, Talüsch", but did not list any particular specimens. Novoselova (1998) proposed the specimen collected in Sarial (and distributed by Hohenacker in the *Unio Itineraria exsiccata*) to be the lectotype. This specimen is not directly connected to the protologue. On the other hand, at LE there are no other specimens clearly connected to the protologue that would be a better choice as lectotype. Thus, I preferred to consider Hohenacker's specimen as neotype in order to avoid any nomenclatural disturbance and considering that it was collected in the area mentioned by Fischer & Meyer (1835), and perfectly fits the original description.

**272. *Geranium peloponnesiacum*** Boiss., Diagn. Pl. Orient. ser. 2, 1: 110. 1854. TYPE LOCALITY: "*G. asphodeloides* Fl. d. Morée ex spec. authentico in

herb. Fauchè non Willd. Hab. in sylvis circâ templum Phigaleae in Peloponneso (herb. Fauchè)". TYPE: Greece. Peloponneso, templum Phigaleae, 37°24'N, 21°51'E, May 1830, J.B. Fauché s.n. (lectotype, designated by Aedo & al. 2007: 118, G-BOISI).

*Perennial herbs*, 20-53 cm tall. *Rootstock* 5.3-13.3 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent to retrorse, eglandular hairs 0.2-2 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves opposite; leaf laminas 3-8.8 cm long, 3.2-10 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.54-0.67], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 4.1-10.8 mm wide at the base [ratio segment width at the base/middle segment length = 0.15-0.24], (11)12-16(17)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.20-0.29]; petioles up to 18 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent to retrorse, eglandular hairs 0.2-2.9 mm long and patent, glandular hairs 0.2-0.3 mm long at the apex; stipules 8.8-12.5 mm long, 1.2-2.4 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 2.1-3.1]; peduncles 14-104 mm long, with uncinat, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.6-1(1.2) mm long and patent, glandular hairs 0.3-0.5 mm long; bracteoles (3.2)3.6-3.4(4.8) mm long, 0.5-0.9 mm wide, linear-lanceolate, whorled; pedicels absent or 5-34 mm long, with uncinat eglan-

dular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.6-1 mm long and patent, glandular hairs 0.3-0.5 mm long. Flowers actinomorphic. *Sepals* 7.2-10.8 mm long, 2.2-3.9 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 1.2-3 mm long [ratio mucro length/sepal length = 0.16-0.41], with  $\pm$  patent eglandular hairs 0.4-3.7 mm long and patent glandular hairs 0.2-0.5 mm long, usually at the base on the abaxial surface, glabrous adaxially. *Petals* (15.4)16.9-18.3(18.9) mm long, 9.5-12.8 mm wide,  $\pm$  patent, emarginate (notch 1.2-3.5 mm deep), without claw, purple, glabrous on the adaxial surface, hairy on the base of the abaxial surface, ciliate on the basal margin, with hairs 0.3-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 6.5-8.4 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 1-3 mm long; anthers 1.8-2.7 mm long, cream with blue edges. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 4.4-8.6 mm long, green. *Fruit* 43.6-44.7 mm long, erect, discharge of seed-ejection type; mericarps 6.3-6.4 mm long, 2.6-3.1 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  patent eglandular hairs 0.3-0.5 mm long and patent, glandular hairs 0.4-0.5 mm long; rostrum 33.7-35.1 mm long, with a narrowed apex 2.1-2.9 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 0.5-0.6 mm long and patent, glandular hairs 0.4-0.5 mm long; stigmatic remnants 2.3-3.2 mm long, with 5 glabrous lobes. *Seeds* 3-3.1 mm long, 2-2.2 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 689, 690.

*Pollen*. *Geranium*-type (Aedo & al. 2007: 99; Bortenschlager 1967: 427).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from April to June.

*Distribution*. This species ranges through central and southern Greece (Fig. 691).

**Habitat.** *Abies* Mill., *Castanea* Mill. and *Quercus* L. forests, on limestone substrates; 550-1500 m.

**Discussion.** *Geranium peloponnesiacum* resembles *G. ibericum* and *G. platypetalum* by its long, soft, patent eglandular hairs along the inflorescence. However, in *G. peloponnesiacum* eglandular hairs are shorter, and petals are hairy on the base of the abaxial surface (petals glabrous on both surfaces in *G. ibericum* and *G. platypetalum*). The leaf lamina is more similar to *G. ibericum* because it has a rhombic middle segment (not obtriangular as in *G. platypetalum*). *Geranium peloponnesiacum* has fewer lobes per segment, and the bracteoles, anthers, staminal filaments and gynoecia are shorter than in both *G. ibericum* and *G. platypetalum*. Additionally, the sepal mucros of *G. peloponnesiacum* are relatively shorter (as in *G. ibericum*), while the petals are more similar in size to *G. platypetalum*. In dry specimens, the leaf abaxial surface of *G. peloponnesiacum* may be a bit whitish, as may also be found in *G. libani*. Nevertheless, the former species has always glandular hairs on the inflorescence, while in the latter they are only eglandular. Additionally, the notch at the apex of the petals is deeper in *G. peloponnesiacum* than in *G. libani*. *Geranium peloponnesiacum* is usually proterandrous, but some specimens with shorter anthers suggest that this species may also show gynodioecy.

**273. *Geranium libani*** P.H. Davis, Notes Roy. Bot. Gard. Edinburgh 22: 25. 1955. *Geranium peloponnesiacum* var. *libanoticum* Boiss. & C.I. Blanche ex Boiss., Diagn. Pl. not coriaceous, not reticulate, with nerves not projected, pilose, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 2.8-6.6 mm wide at the base [ratio segment width at the base/middle segment length = 0.10-0.23], (11)14-15(21)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.32-0.55]; petioles up to 18 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinete, eglandular hairs 0.1-0.3 mm long; stipules 3.9-14.1 mm long, 1.3-2.8 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1.2-3.1]; peduncles 1.3-91 mm long, with uncinete, eglandular hairs 0.1-0.3 mm long; bracteoles (2.3)3.7-5.2(5.7) mm long, 0.6-1.3 mm wide, linear-lanceolate, whorled; pedicels absent or 4-24 mm long, with uncinete eglandular hairs 0.1-0.3 mm long and patent, eglandular hairs 0.4-1 mm long. Flowers actinomorphic. *Sepals* 7.2-10.9 mm long, 2.9-5.5 mm wide, lanceolate, smooth, not accrescent, nerves 5-7, mucro 1.9-2.8 mm long [ratio mucro length/sepal length = 0.22-0.38], with uncinete eglandular hairs 0.1-0.3 mm long and  $\pm$  patent eglandular hairs 0.4-2.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.1)15.4-16.7(20) mm long, 8.4-14.2 mm wide, patent, emarginate (notch 1.1-3.2 mm deep), without claw, blue, glabrous on both surfaces, ciliate on the basal and, sometimes, on the apical margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.2-9.9 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-2.5 mm long; anthers 1.8-2.5 mm long, blue. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.3-9.1 mm long, dark purple. *Fruit* 29.7-37.5 mm long, erect, discharge of seed-ejection type; mericarps 5.2-

5.9 mm long, 2-2.8 mm wide, without a strand of fibers, compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  patent eglandular hairs 0.2-2.2 mm long; rostrum 20.8-29.2 mm long, with a narrowed apex 2.2-4.7 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 0.2-1.7 mm long; stigmatic remnants 1.8-3.2

mm long, with 5 glabrous lobes. *Seeds* 3.1-4.2 mm long, 1.7-2.4 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 695.

*Pollen*. *Geranium*-type (Aedo & al. 2007: 99).

*Chromosome number*.  $2n = 28, 56$ .

*Phenology*. Collected in flower from May to August.

Achishkho, bank of Beshenka river, 43°43'N, 40°7'E, 2 July 2006, *Naumenko & al. s.n.* (MA). **Turkey.** ARTVIN: Batum, in monte Egre-su, 41°13'N, 42°27'E, 2 July 1912, *Holmberg 2081* (BM, S, UPS).

**Discussion.** *Geranium gymnocaulon* is sometimes mistaken for specimens

of *G. ibericum* without glandular hairs. However, *G. gymnocaulon* has a characteristic indumentum on the peduncles and pedicels composed of short, uncinat hairs, lacking the long, soft, patent, eglandular hairs of *G. ibericum*. From *G. libani* (which has an indumentum quite similar to *G. ibericum*), it can be further distinguished by its petal indumentum which are glabrous on both surfaces, as opposed to *G. libani*, where the petals are hairy on the base of the abaxial surface, and by having a deeper notch at the petal apex. Some specimens of *G. gymnocaulon* have the basal part of the stem almost glabrous.

**275. *Geranium kurdicum* Bornm.,** Repert. Spec. Nov. Regni Veg. 8: 82. 1910. TYPE LOCALITY: "Assyria: In pratis alpinis montis Helgurd ditionis oppidi Riwandus, Karduchiae austro-orientalis, alt. 22-2900 m s. m.; 26. Juni 1893, legi (Bornm., iter Persico-turcic. a. 1892-93, no. 998)". TYPE: Iraq. Assyria, montis Helgurd ditionis oppidi Riwandus, Karduchiae austro-orientalis, 36°46'N, 44°51'E, 26 June 1893, *J. Bornmuller 998* (lectotype, designated by Knuth 1912: 141, B destroyed; lectotype, here designated, LD-1089997!; isolectotypes, BR-0000008258618!, JE!, K-000074056!, WI!, WU!).

**Perennial herbs,** 10-43 cm tall. **Rootstock** 3.8-10.8 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, glabrous or with scattered patent to retrorse, eglandular hairs 0.1-0.3 mm long. **Basal leaves** in a ± persistent rosette, cauline leaves opposite; leaf laminas 2.4-5.5 cm long, 3.2-6.9 cm wide, not peltate, deeply palmatifid [ratio main-sinus length/middle segment length = 0.71-0.84(0.90)], polygonal in outline, base cordate, not coriaceous, not reticulate, with nerves not projected, pilose, with scattered, appressed,

eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 0.7-5.6 mm wide at the base [ratio segment width at the base/middle segment length = 0.03-0.15], (5)7-10(12)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.28-0.68]; petioles up to 19 cm long, without abscission zone, terete, not swollen, not deflexed in age, glabrous or with scattered, patent to retrorse, eglandular hairs 0.1-0.2 mm long; stipules 3.5-7.6 mm long, 1.2-1.7 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 2-4.9]; peduncles 18-101 mm long, with scattered patent to retrorse, eglandular hairs 0.1-0.7 mm long; bracteoles (1.9)2.4-3.1(4.6) mm long, 0.5-0.8 mm wide, linear-lanceolate, whorled; pedicels absent or 9-34 mm long, with scattered patent to retrorse eglandular hairs 0.2-0.7 mm long. Flowers actinomorphic. *Sepals* 6.7-9.2 mm long, 3-4.5 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.7-2.7 mm long [ratio mucro length/sepal length = 0.10-0.30], with  $\pm$  patent eglandular hairs 0.8-1.5 mm long on the abaxial surface, glabrous adaxially. *Petals* (9.8)12.8-14.1(15.2) mm long, 7.9-11.1 mm wide, erect-patent, emarginate (notch 0.9-2.5 mm deep), without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 5.3-7.6 mm long, lanceolate, pink, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.5-1.2 mm long; anthers 1.7-2.5 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5-7.4 mm long, dark purple. *Fruit* 23.4-30.2 mm long, erect, discharge of seed-ejection type; mericarps 4.2-4.9 mm long, 1.7-2.2 mm wide, without a strand of fibers, compressed at the apex,

smooth, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  patent eglandular hairs 0.4-1.5 mm long; rostrum 16.2-23.3 mm long, with a narrowed apex 1-2.9 mm long, twisted distally, with  $\pm$  patent, eglandular hairs 0.2-0.6 mm long; stigmatic remnants 1.2-1.5 mm long, with 5 glabrous lobes. *Seeds* 3.1 mm

long, 1.6 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons not studied. Fig. 697.

*Pollen*. *Geranium*-type (Aedo & al. 2007: 99).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from June to September.

Fig. 698. Distribution of *Geranium kurdicum*.

**Distribution.** This species ranges from southeastern Turkey to northern Iraq (Fig. 698).

**Habitat.** Moist areas of alpine meadows; 2200-3500 m.

**Additional specimens examined.** **Iraq.** ERBIL: Arl Gird Dag, 36°45'N, 44°51'E, 24 July 1932, *Guest* 2905 (K); N & W slopes in Helgord, 36°45'N, 44°51'E, 15 Aug. 1956, *Haley* 136 (BM, K); Sarcal, ped montis Helgurd, 36°46'N, 44°51'E, 7 June 1960, *Hadac* 2152 (PR); Helgurd, NW, 36°46'N, 44°51'E, 7 June 1960, *Prosser* 2443 (PR); N of Helgord Range near Berma Sand Lake, 36°46'N, 44°51'E, 3 Sep. 1957, *Rawi* 24776 (K). **Turkey.** BITLIS: Van, Satak, Kavussahap Dag, 38°15'N, 42°15'E, 23 July 1954, *Davis* 23217 (BM); Bitlis, Kambos Dag above Hurmuz, 38°17'N, 41°58'E, 30 June 1954, *Davis* 23386 (BM, K). HAKKÂRI: Cilo Tepe, 37°30'N, 44°0'E, 8 Aug. 1954, *Davis* 24034 (BM, K); Kara Dag, 37°42'N, 43°42'E, 15 Aug. 1954, *Davis* 24403 (BM, K).

**Discussion.** *Geranium kurdicum* can be easily distinguished from other species of sect. *Lanuginosa* by its deeply palmatifid leaves with deep and narrow secondary divisions. This species is glabrous or with scattered eglandular hairs on stem and petioles, and shows a more dense indumentum on peduncles and pedicels. In *G. kurdicum*, petal indumentum is similar to *G. gracile*, with hairs on the base of adaxial surface, although in the latter species petals are relatively longer and narrower.

**IV. *Geranium* subg. *Robertium*** (Picard) Rouy, in Rouy & Foucaud, Fl. France 4: 94. 1897. TYPE: *Geranium robertianum* L. (art. 10.8).

**Fruit** of carpel-projection type. At dispersal, the whole mericarp, containing the seed, is ejected by the propelling force of the explosive recurvature of the awn, while the awn remains attached to the columella. In sect. *Divaricata* the rostrum is not well developed, and thus the mericarp including the seed is shortly ejected.

**IVa. *Geranium* sect. *Batrachioidea*** W.D.J. Koch, Syn. Fl. Germ. Helv. 1: 139. 1835, ["batrachioides"]. *Geranium* sect. *Pyrenaica* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 46, 152. 1912. TYPE: *Geranium pyrenaicum* Burm. f. (designated by Yeo 1984: 15).

**Herbs** annual or perennial. **Flowers** actinomorphic. **Petals** emarginate, without claw. **Pollen** of *Geranium*-type. **Fruit** of carpel-projection type, operative; mericarps smooth or transversely wrinkled; rostrum not twisted. **Cotyledons** with entire margins.

**276. *Geranium aequale*** (Bab.) Aedo, Anales Jard. Bot. Madrid 55(2): 466. 1997. *Geranium molle* var. *aequale* Bab., Man. Brit. Bot. ed. 2, 65. 1847. TYPE LOCALITY: "near Leamington (1845). Mr. J.J. Murcott". TYPE: Great Britain. England, near Leamington, 52°15'N, 1°29'W, June 1845, *J.J. Murcott s.n.* (lectotype, designated by Carolin 1965: 333, CGE-05773!).

*Geranium molle* f. *preuschoffii* Abrom., Fl. Ost- & Westpreussen: 156. 1898. TYPE LOCALITY: "Wpr. Mbg. Pfarrgarten in Tannsee (Pff. 81)". TYPE: Germany. Westpreussen, Magdeburg, Pfarrgarten in Tannsee, 51°43'N, 10°43'E, *J. Abromeit s.n.* (no original material located).

**Annual herbs**, 5-40 cm tall. **Stem** erect or ascending, leafy, with pat-

ent, eglandular hairs 0.1-2.1 mm long and patent, glandular hairs 0.1-0.2 mm long. **Basal leaves** in a persistent rosette, cauline leaves alternate; leaf laminae 1-3(5) cm long, 1.3-3.7(5.8) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.60-0.75], orbicular to reniform in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment obtriangular, 1.4-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.17-0.26], 3(6)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.18-0.28]; petioles up to 24 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-1.6 mm long and patent, glandular hairs 0.2-0.3 mm long; stipules 2.6-7 mm long, 1.1-4 mm wide, ovate-lanceolate (sometimes with a short bifid apex), free, papery, brown, with eglandular hairs on abaxial surface, glabrous adaxially. **Inflorescence** a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.9-4.1]; peduncles 10-45(70) mm long, with patent, eglandular hairs 0.4-1.7 mm long and patent, glandular 0.1-0.2 mm long; bracteoles 0.9-3 mm long, 0.4-1.5 mm wide, lanceolate, sometimes lobed, whorled; pedicels 6.2-22 mm long, with patent, eglandular hairs 0.4-1.8 mm long and patent, glandular hairs 0.1-0.2 mm long. **Flowers** actinomorphic. **Sepals** (2.8)3.3-4(5) mm long, 1.4-2.1 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.3 mm long [ratio mucro length/sepal length = 0.02-0.08], with patent, eglandular hairs 0.3-2 mm long and ± patent, glandular hairs 0.1-0.2 mm long on the abaxial surface, glabrous adaxially. **Petals** 1.6-3(4.6) mm long, 1-3 mm wide, erect-patent, emarginate (notch 0.2-1 mm deep), without claw, bright purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.3 mm long. **Stamens**

10, both whorls bearing anthers; filaments 1.5-4.5 mm long, lanceolate, white with pink apex, glabrous except for a some cilia 0.1-0.2 mm long on the proximal half; anthers 0.4-0.6 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.6-5 mm long, purple. *Fruit* 9-13.1 mm long, erect, discharge of carpel-projection type, operative; mericarps 1.3-1.9 mm long, 0.8-1.3 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, glabrous over most of the surface, densely ciliate at the base; rostrum 5.8-10.5 mm long, with a narrowed apex 0.5-1.5 mm long, not twisted, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.9-2 mm long, with 5 hairy lobes. *Seeds* 1.2-1.7 mm long, 0.7-1.2 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with entire margin. Fig. 699.

*Pollen*. Ornamentation not studied.

*Chromosome number*.  $2n = 26$ .

*Phenology*. Collected in flower from February to July.

*Distribution*. This species ranges through western Europe and it is introduced in U.S.A., southern Argentina and New Zealand (Fig. 700).

*Habitat*. Dry areas near villages, cultivated fields, open grass-covered hill-sides, and edge of forests; 0-1600 m.

*Representative specimens examined*.

**Discussion.** *Geranium* subg. *Robertium* exhibits several different patterns of mericarp ornamentation, which are useful to differentiate the species. Thus, the absence of such ornamentation should also be of relevance. Consequently, I decided to recognize *G. aequale* as specifically distinct from *G. molle*. *Geranium aequale* is close to *G. molle*, from which it is easily distinguished by its smooth, densely ciliate mericarps (those in *G. molle* are transversely wrinkled and sparsely ciliate at the base). Moreover, the mericarps of *G. aequale* do not cover the seed completely, as in *G. molle*. The seeds of *G. aequale* have a thick testa, which may compensate for the slight protection provided by the mericarp. I was not able to find any intermediates between *G. aequale* and *G. molle*.

Clement (1997), Lawalrée (2000) and Veldkamp (2008) recorded some localities of this usually overlooked species from England, Belgium and The Netherlands respectively.

*Annual herbs*, 10-45 cm tall. *Stem* erect or ascending, leafy, with long patent, eglandular hairs 1-2.5 mm long and short, patent, glandular and eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a persistent rosette, cauline leaves alternate; leaf laminae 0.9-4(8.2) cm long, 0.9-5.2(8.6) cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.54-0.75], orbicular to reniform in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment obtriangular, 1.5-5(12.1) mm wide at the base [ratio segment width at the base/middle segment length = 0.21-0.27], 3-4(14)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.14-0.26]; petioles up to 28 cm long, without abscission zone,

terete, not swollen, not deflexed in age, with patent, eglandular hairs 1-1.5 mm long and short, patent, eglandular and glandular hairs 0.2-0.5 mm long; stipules 3.6-10.9 mm long, 1.2-4 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 0.7-1.3]; peduncles 5-80 mm long, with patent, eglandular hairs 1-2.2 mm long and short, patent, eglandular and glandular hairs 0.1-0.5 mm long; bracteoles 1-5 mm long, 0.3-1.2 mm wide, lanceolate, whorled; pedicels 5-28 mm long, with patent, eglandular hairs 1-1.8 mm long and short (0.2-0.5 mm long) patent, eglandular and glandular hairs. Flowers actinomorphic. *Sepals* (1)2.5-5.5(6) mm long, 0.9-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.2-0.3 mm long [ratio mucro length/sepal length = 0.03-0.10], with patent, eglandular hairs 1-2 mm long and  $\pm$  patent, eglandular and glandular hairs 0.2-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* 3-8.5(10.5) mm long, 1.5-7 mm wide, erect-patent, emarginate (notch 0.7-2.5 mm deep), without claw, bright purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2-5 mm long, lanceolate, white, glabrous except for a some cilia 0.1-0.2 mm long on the proximal half; anthers 0.3-1.5 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.4-6 mm long, purple. *Fruit* 8-14 mm long, erect, discharge of carpel-projection type, operative; mericarps 1.6-2.1 mm long, 1.1-1.4 mm wide, without a strand of fibers, not compressed at the apex, transversely wrinkled, without basal beak, without a basal callus, without a basal prong, brown, glabrous on the surface, with a few cilia at the base; rostrum 6-11 mm long, with a narrowed apex 1-3 mm long, not twisted, with erect-patent, eglan-

dular hairs 0.1-0.3 mm long; stigmatic remnants 1-2 mm long, with 5 hairy lobes. *Seeds* 1.4-1.8 mm long, 1-1.2 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 701, 702.

*Pollen*. *Geranium*-type (Bortenschlager 1967: 425; Park & Kim 1997: 314; Shehata 2008: 69; Stafford & Blackmore 1991: 62; Velasco 1992b: 59).

*Chromosome number*.  $2n = 26$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from Europe and northern Africa to western Himalayas, and it is introduced in southwestern Canada, U.S.A., southern South America, South Africa, Hawaii, Taiwan, Australia and New Zealand (Fig. 703).

*Habitat*. Roadsides, cultivated areas, waste places, open meadows, dunes, dry grassland, and edge of forests; 0-2500 m.

*Representative specimens examined*.

**Discussion.** *Geranium molle* is a very distinctive species, easily identified by its transversely wrinkled mericarp, glabrous on the surface and sparsely ciliate at the base. It grows naturally almost throughout Europe, in the circum-Mediterranean

area, Macaronesia, and central and western Asia. The eastern limit in Europe is not well known, because of the scarcity of herbarium material. In Asia, this species reaches the western Himalayas to 76°E in India. It has been introduced in many temperate areas of North America, South America, southern Africa, Hawaii, Taiwan and Australia. *Geranium molle* shares some characters with *G. aequale*, such as glabrous stamen filaments, an abruptly tapered fruit rostrum, and glabrous mericarp surface, supporting their close relationship.

A number of minor morphological variants of *G. molle* have been recognized in the literature, of which the most notable seems to be *G. brutium*. According to Webb & Ferguson (1968: 198), this is an eastern Mediterranean species similar to *G. molle* but frequently perennial (*G. molle* was considered annual by these authors), with the lowermost inflorescence leaves shorter than the peduncle or slightly exceeding it (as opposed to considerably longer in *G. molle*) and with petals 6-11 mm long (3-7 mm long in *G. molle*). Davis (1967: 460) and Persson (1987: 547) considered *G. brutium* as a subspecies of *G. molle*, whereas Pignatti (1982: 10) preferred specific rank. All of these authors used the above-mentioned characters to recognize *G. brutium*. All the studied material identified (by several authors) as *G. brutium* is clearly annual, though variable in stature and robustness. This was already pointed out by Boissier (1867: 880, 882). *Geranium molle* subsp. *sinjaricum*, described by Al-Shehbaz & al. (1983: 353) from Iraq, was said to be perennial. Unfortunately, I was not able to examine any original material on which this name was based, but all specimens studied from Iraq were annuals. The ratio between the length of the lowest inflorescence leaf and the peduncle varies considerably in *G. molle*, but independently of plant robustness and petal length. This suggests that *G. brutium* has been distinguished from *G. molle*

only because of its longer petals. However, some plants with long petals can be found throughout the geographic range of *G. molle*, even in populations with mainly short petals. According to Yeo (*pers. comm.*) and my own observations, the earliest flowers usually exhibit the longest petals, with petal length diminishing as the season progresses. Moreover, the type specimen of *G. brutium* has petals 7.8 mm long, not far from the *G. molle* values. Consequently, the forms with long petals are here not accorded taxonomic recognition. Sometimes it is possible to find depauperate plants of *G. molle* (up to 5 cm high), fertile but with the leaves not fully developed. Some such specimens [e.g., *Florstrom s.n.* (K) from Finland, or *Davis & Bokhari 55856* (K) from Iran] have leaves with undivided lobes. However, no other character state is associated with this size reduction, which suggests that this form also does not deserve taxonomic recognition.

The chromosome number  $2n = 28$  attributed to this species (Martin & al. 2022) should be confirmed. Carolin (1965) designated as type of *G. molle* a drawing by Vaillant (1727) that shows a branch and a detail of a flower. In this drawing the ornamentation of the mericarps, nor the indumentum of the plant or its annual life span cannot be appreciated. Therefore an epitype is designate for purposes of the precise application of the name.

*Annual herbs*, 10-50 cm tall. *Stem* erect or ascending, leafy, with patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.1-0.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 1.5-3.8 cm long, 1.5-4.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.30-0.75], orbicular to reni-

form in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 2-4 mm wide at the base [ratio segment width at the base/middle segment length = 0.18-0.21], 3(5)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.16-0.29]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.1-0.2 mm long; stipules 2-4 mm long, 1-1.5 mm wide, lanceolate, free, papery, brown, with eglandular hairs on abaxial surface, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.9)1-3.7]; peduncles 5-32 mm long, with patent, eglandular and glandular hairs 0.1-0.3 mm; bracteoles 1.5-2 mm long, 0.4-0.5 mm wide, linear-lanceolate, whorled; pedicels 6-16 mm long, with patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.1-0.2 mm long. Flowers actinomorphic. *Sepals* 3-4.5 mm long, 1.5-2 mm wide, lanceolate, smooth, not accrescent, nerves 3-5, mucro 0.1-0.2 mm long [ratio mucro length/sepal length = 0.02-0.03], with patent, eglandular hairs 0.6-1 mm long and ± patent, eglandular and glandular hairs 0.2-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* 2-3 mm long, 1-1.5 mm wide, erect-patent, emarginate (notch 0.2-0.5 mm deep), without claw, pale purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, external whorl lacking anthers; filaments 1.2-1.5 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers 0.2-0.4 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 1.7-3 mm long, yellow. *Fruit* 8.9-11 mm long, erect, discharge of carpel-projection type, operative; mericarps 1.6-2.2 mm long, 0.8-1.1

mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with appressed, eglandular hairs 0.1-0.2 mm long on all the surface and a few cilia at the base; rostrum 6.3-9 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular and glandular hairs 0.1-0.2 mm long; stigmatic remnants 0.5-0.7 mm long, with 5 hairy lobes. *Seeds* 1.5-1.8 mm long, 0.8-1.1 mm wide, finely reticulate, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 704, 705.

**Pollen.** *Geranium*-type (Bortenschlager 1967: 425; Stafford & Blackmore 1991: 78; Velasco 1992b: 59).

**Chromosome number.**  $2n = 26, 34?$

**Phenology.** Collected in flower from March to December.

**Distribution.** This species ranges through Europe to central Asia (to northern Pakistan) and northern Africa, and it is introduced in North America, southern South America, eastern Siberia, Taiwan, Hawaii and New Zealand (Fig. 706).

**Habitat.** Cultivated areas, waste places, rocky slopes, and dry grassland, meadows, and edge of forests; 0-2550 m.

**Discussion.** *Geranium pusillum* has only five anther-bearing stamens, a rare feature in *Geranium*, which is also found in *G. texanum*. Both species are easily distinguished by the type of fruit, which is of the carpel-projection type in the former and of the seed-ejection type in the latter. *Geranium pusillum* has been frequently confused with *G. pyrenaicum*, a closely related perennial species with ten anther-bearing stamens. It is also often confused with *G. rotundifolium*, another widespread annual species. However, *G. rotundifolium*, a member of subgenus *Geranium*, has typical seed-ejection fruits, reticulate seeds, and ten anther-bearing stamens. *Geranium pusillum* is indigenous in the Eurasian portion of its range. The eastern limit of *G. pusillum* in Europe is not well known, because of the scarcity of herbarium material. In Asia, this species reaches the western Himalayas to 75°E in Jammu-Kashmir. *Geranium pusillum* has been introduced to many temperate areas of North America, South America, eastern Siberia, Taiwan, Hawaii and New Zealand.

The name *G. pusillum* has often been attributed to "Burm. f., Spec. Bot. Geran. 1759"; however, that work was published on 17 August, about two months after the Linnaean protologue. According to Van Loon (1984c: 283) the chromosome numbers  $2n = 34$  attributed to this species should be disregarded.

---

**279. *Geranium pyrenaicum*** Burm. f., Spec. Bot. Geran. 27. 1759, [nom. cons.]. TYPE LOCALITY: "Habitat in Pyrenaeis". TYPE: Spain. Lérida, Alto Anéu, Pla de la Dinada, 42°39'N, 1°00'E, 7 July 1992, *S. Castroviejo & al. 12009* (conserved type by Aedo & Fumaux 2012: 256, MA-512048).

*Perennial herbs*, 15-70(110) cm tall. *Rootstock* 3.5-11.2 mm in diameter, vertical, not tuberculate, not turnip-shaped, without thickened roots.

*Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with long, patent, eglandular hairs 0.9-1.4 mm long and short, patent, eglandular and glandular hairs 0.1-0.5 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae 2.8-6.9 cm long, 2.5-7.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.50-0.72], orbicular to reniform in outline, base cordate, not coriaceous, with nerves not projected, with appressed, eglandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 4-14.5 mm wide at the base [ratio segment width at the base/middle segment length = 0.23-0.43], (3)7-10(12)-lobed at the apex [ratio secondary sinus length/middle segment length = 0.08-0.24]; petioles up to 25 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 1-1.5 mm long, and short, patent, eglandular and glandular hairs 0.1-0.5 mm long; stipules 3-11.2 mm long, 0.9-5.2 mm wide, lanceolate (sometimes with a short bifid apex), free, papery, brown, with eglandular hairs on abaxial surface, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1-3.6]; peduncles 10-46 mm long, with patent, eglandular hairs 0.8-1.4 mm long and short, patent, eglandular and glandular hairs 0.1-0.5 mm long; bracteoles 2.5-5 mm long, 0.5-0.8 mm wide, lanceolate, sometimes lobed, whorled; pedicels 10-30 mm long, with patent, eglandular and glandular hairs 0.1-0.5 mm long and, sometimes, patent, eglandular hairs (0.5) 0.7-1.3 mm long. Flowers actinomorphic. *Sepals* 3.2-5.6 mm long, 1.6-2.5 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.2-0.4 mm long [ratio mucro length/sepal length = 0.05-0.09], with ± patent, eglandular and glandular hairs 0.1-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 7-11 mm long, 3.6-6.5 mm wide, erect-patent, emar-

ginate (notch 1-3 mm deep), without claw, bright purple, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.7-5 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long; anthers 0.6-1.2 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3.2-4.5 mm long, purple. *Fruit* 13.9-20 mm long, erect, discharge of carpel-projection type, operative; mericarps 2.4-3.3 mm long, 1.1-1.6 mm wide, without a strand of fibers, not compressed at the apex, smooth, without basal beak, without a basal callus, without a basal prong, brown, with appressed, eglandular hairs ca. 0.1 mm long or glabrous, not ciliate at the base, rarely glabrous; rostrum 8.5-15 mm long, without a narrowed apex, not twisted, with erect-patent, eglandular and glandular hairs 0.1-0.2 mm long; stigmatic remnants 1.5-1.8 mm long, with 5 hairy lobes. *Seeds* 2-2.7 mm long, 0.7-1.4 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin.

*Pollen.* *Geranium*-type (Bortenschlager 1967: 431; Gagnepain 1903: 86; Velasco 1992b: 59).

*Chromosome number.*  $2n = 20, 22-24, 28$ .

*Phenology.* Collected in flower from January to October.

*Distribution.* This species ranges from Europe to western Asia (to northern Iran) and northwestern Africa and it is introduced in Canada, U.S.A. and Australia.

*Habitat.* Roadsides, waste places, field margins, and forest edges; 0-2650 m.

1. Mericarps with appressed, eglandular hairs; pedicels with patent, eglandular and glandular hairs 0.1-0.5 mm long and, rarely, patent, eglandular hairs 0.7-1.3 mm long.

#### **279a. subsp. pyrenaicum**

1. Mericarps glabrous; pedicels with patent, eglandular and glandular hairs 0.1-0.2 mm long and, usually,

patent, eglandular hairs (0.5)0.7-1.3 mm long. **279b. subsp. lusitanicum**

#### **279a. Geranium pyrenaicum** Burm. f. subsp. **pyrenaicum**

*Geranium perenne* Huds., Fl. Angl.: 265. 1762. TYPE LOCALITY: "Habitat in pratis montanis. Ad ripam fluvii inter Bingley et Kighley in agro Eboracensis; prope Enfield, et inter Hyde-Park et Little-Chelsea". TYPE: Great Britain. England, locality and collector unknown (lectotype, designated by Aedo & al. 1998: 611, LINN-858.80 image!).

*Geranium umbrosum* Waldst. & Kit. in Waldst., Descr. Icon. Pl. Hung. 2: 131, tab. 124. 1803-1805. *Geranium pyrenaicum* var. *umbrosum* (Waldst. & Kit.) DC., Prodr. 1: 643. 1824. *Geranium pyrenaicum* subvar. *umbrosum* (Waldst. & Kit.) Nyman, Consp. Fl. Eur. 137. 1878. *Geranium pyrenaicum* [b] *umbrosum* (Waldst. & Kit.) Graebn. in Asch. & Graebn., Syn. Mitteleur. Fl. 7(1): 33. 1913. TYPE LOCALITY: "Crescit in umbrosis ad thermas Herculis, Julio florens". TYPE: Hungary. *P. Kitaibel* s.n. (lectotype, designated by Aedo & al. 1998: 615, BM-000751348; isolecto, PR-155805!).

*Geranium pyrenaicum* var. *pumilum* Picard, Mém. Soc. Agric. Boulogne-sur-Mer 1: 131. 1837. TYPE LOCALITY: "L'espèce et la variété croissent dans les mêmes lieux, ... Cette belle espèce n'est point comprise parmi celles de la flore de la Somme; néanmoins on l'avait déjà trouvée plusieurs fois. Ainse M. Baillon possède un échantillon qu'il a ramassé, il y a plus de vingt ans, dans la cour de l'hôpital; moi-même, depuis plus de dix ans, je l'avais recueillie à Amiens; enfin M. Boucher, dans son catalogue, l'indique à la porte St.-Gilles; mais M. Baillon regardait sa plante comme semée par hasard. Mes échantillons étaient restés confondus avec d'autres espèces dans mon herbier; le catalogue des plantes d'Abbeville et de ses environs ne semblait pas une preuve suffisante aux yeux des botanistes, parce que cet ouvrage contient l'indication d'une foule de plantes exotiques qui ont pu être trouvées quelquefois parmi les décombres, sans que l'on puisse, raisonnablement, por ce fait, les considérer comme indigènes. Ceci explique comment le *G. pyrenaicum* parut nouveau à tous les amateurs, lorsque, en 1834, je le retrouvai précisément dans la localité indiquée autrefois par M. Boucher. On la trouve à Abbeville, sur le versant du rempart, du côté du champs de Foire, et à la porte St.-Gilles, dans les fortifications; à Amiens, sur le rempart, auprès du Jardin des Plantes, et dans le jardin même, sur le petit rideau qui se trouve au-devant de la salle des Démonstrations". SYNTYPES:

France. À Abbeville, 50°06'N, 1°50'E, sur le versant du rempart, du côté du champs de Foire, et à la porte St.-Gilles, dans les fortifications; à Amiens, 49°53'N, 2°17'E, sur le rempart, auprès du Jardin des Plantes, et dans le jardin même, sur le petit rideau qui se trouve au-devant de la salle des Démonstrations, *C. Picard* s.n. (no original material located).

*Geranium minae* Tineo, Pl. Rar. Sicil.: 25. 1846, ["Minnae"]. *Geranium pyrenaicum* var. *minae* (Tineo) Nyman, Consp. Fl. Eur.: 138. 1878. TYPE LOCALITY: "In elatioribus montosis, apricis, lapidosis; var. [α] Isnello alla Costa dell oro; al Ferro Minà; [β] Monte di Cammarata". TYPE: Italy. monte Ferro, 37°53'N, 14°01'E, *F. Minà* 514 (lectotype, designated by Aedo & al. 1998: 615, PALI).

**Discussion.** *Geranium pyrenaicum* is the only perennial species in section *Batrachioidea*. *Geranium pusillum* seems to be the closest relative of *G. pyrenaicum*. The mericarps of *G. pyrenaicum* are quite similar to those of *G. pusillum*: smooth, with appressed eglandular hairs (except for subsp. *lusitanicum*), but slightly smaller. As the remaining species of the section, both species have emarginate petals and the chromosome number  $2n = 26$ .

*Geranium pyrenaicum* grows naturally in almost all of Europe, the Caucasus, Asia Minor, northern Iran, and northwest Africa. It has been introduced in some temperate areas of northeastern North America, Australia and probably in central and northern Europe (Brandes 2004; Ciaciura 2001).

Among the great number of morphological variants formally described

under *Geranium pyrenaicum*, only that here segregated as subspecies *lusitanicum* seems of some importance. *Geranium pyrenaicum* subsp. *lusitanicum* comprises plants from northwestern Spain and Portugal with glabrous mericarps and long, patent, eglandular hairs on the peduncles and pedicels. In this area, all specimens examined exhibit these features. However, eastward, in the eastern portion of the Cantabrian range and in the Iberian range, where the two subspecies occur sympatrically, the indumentum of the peduncles and pedicels is variable. This was pointed out by Ortiz (1989: 243), who proposed subspecific rank for these entities. The rank of subspecies is here used according to Du Rietz (1930), for allopatric taxa merging morphologically where they come into contact. Lidén (1986) described subspecies as “taxa believed to be allopatrically evolved from a common ancestor, not sufficiently different to be recognized as species, i.e. resulting from primary speciation at an early stage”. This could be the case in *G. pyrenaicum*, considering its geographical distribution and weak morphological divergence. I consider occasional specimens with glabrous mericarps from within the geographic range of *G. pyrenaicum* subsp. *pyrenaicum* to be discordant elements representing minor variation of no taxonomic relevance. However, if such individuals were confirmed as more common, the status of subsp. *lusitanicum* would have to be reconsidered. It seems that some chromosome numbers different to  $2n = 26$  attributed to this species should be disregarded (Van Loon 1984b: 270).

**IvB. *Geranium* sect. *Divaricata*** Rouy in Rouy & Foucaud, Fl. France 4: 88. 1897. TYPE. *Geranium divaricatum* Ehrh. (art. 10.8).

*Annual or perennial herbs. Flowers actinomorphic. Petals* emarginate, without claw. *Pollen* of *Geranium*-type.

*Fruit* of carpel-projection type, inoperative; mericarps with transverse ribs; rostrum not twisted. *Cotyledons* with a notch on each side.

**280. *Geranium albanum*** M. Bieb., Fl. Taur.-Caucas. 2: 137. 1808. TYPE LOCALITY: “Crescit in Albaniâ ibericâ, circa pagum Wakiri. D. Steven”. TYPE: Georgia. **Discussion.** *Geranium albanum* is a perennial species endemic to northern Iran and the Caucasus. It has a singular mericarp, with a very thick wall and a well-developed dorsal crest. Features shared with *G. divaricatum* are the inoperative discharge mechanism and the ribbed mericarp. The chromosome number in this species is not fully clarified. Warburg (1938a: 145) and Van Loon (1984a: 276) have given different numbers, with only that of the first author matches with data for *G. divaricatum*.

**281. *Geranium divaricatum*** Ehrh., Beitr. Naturk. 7: 164. 1792. *Geranium winterlii* Roth, Catal. Bot. 2: 78. 1800, nom. illeg., ["winterli"]. TYPE LOCALITY: "Hungaria. J.J. Winterl, Prof. ... *Geranium novum*. Winterl. ind.". TYPE: Hungary. *Ehrhart Plant. Select.* 69 (lectotype, designated by Aedo 1998: 620, M!; isolectotype, GOET-004058 image!).

*Geranium divaricatum* var. *ambiguum* Rochel ex Schult., Oestr. Fl. ed. 2, 2: 285. 1814. *Geranium divaricatum* [B] *ambiguum* (Rochel ex Schult.) Graebn. in Asch. & Graebn., Syn. Mitteleur. **Annual herbs**, 20-50 cm tall. *Stem* erect, leafy, with long patent, eglandular hairs 1-3 mm long and short, patent, glandular and eglandular hairs 0.2-0.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves

alternate; leaf laminae 2.5-7 cm long, 3.1-7.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.65-0.85], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± appressed, eglandular and glandular hairs on both surfaces; segments 5(7), in 1 plane, middle segment rhombic, 4-9 mm wide at the base [ratio segment width at the base/middle segment length = 0.18-0.21], 7-12(15)-lobed in distal half [ratio secondary sinus length/middle segment length = 0.16-0.26]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 1-2.8 mm long and short, patent, eglandular and glandular hairs 0.2-0.5 mm long; stipules 4-7 mm long, 1-2 mm wide, lanceolate, free, papery, brown, with eglandular and glandular hairs on abaxial surface, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 1.2-1.3]; peduncles 6-35 mm long, with patent, eglandular hairs 1-3.5 mm long and short, patent, eglandular and glandular hairs 0.1-0.5 mm long; bracteoles 3-4 mm long, 0.5-1 mm wide, lanceolate, whorled; pedicels 10-28 mm long, with patent, eglandular hairs 1-2.5 mm long and short, patent, eglandular and glandular hairs 0.2-0.5 mm long. Flowers actinomorphic. *Sepals* 4-4.5 mm long, 1.8-2 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.7-1 mm long [ratio mucro length/sepal length = 0.10-0.22], with patent, eglandular hairs 0.2-0.8 mm long and patent, glandular hairs 0.3-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* 4-6.5 mm long, 2.5-3 mm wide, erect-patent, emarginate (notch ca. 1 mm deep), without claw, bright purple, glabrous on both surfaces, sometimes ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 1-2.5 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.1-0.2 mm long;

anthers 0.4-0.6 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 3-3.5 mm long, pale pink. *Fruit* 7-11 mm long, erect, discharge of carpel-projection type, inoperative; mericarps 2.8-3.5 mm long, 2-1.8 mm wide, without a strand of fibers, not compressed at the apex, with 3-4 transverse ribs, without a longitudinal crest, without basal beak, without a basal callus, without a basal prong, brown, with ± appressed, eglandular hairs 0.2-0.5 mm long, not ciliate at the base; rostrum 5-8 (0.5-0.6 mm wide at the base) mm long, without a narrowed apex, not twisted, with erect-patent, eglandular and glandular hairs 0.1-0.2 mm long; stigmatic remnants 0.5-1 mm long, with 5 hairy lobes. *Seeds* 2.4-2.6 mm long, 1.3-1.4 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with a notch on each side margin. Figs. 713, 714.

**Pollen.** *Geranium*-type (Velasco 1992b: 58).

**Chromosome number.**  $2n = 26$ .

**Phenology.** Collected in flower from April to August.

**Distribution.** This species ranges from Spain, through central and eastern Europe and western Asia to western Himalayas, China and central Siberia (Fig. 715).

**Habitat.** Waste places, meadows, stony dry slopes, field margins, and shady wood borders; 50-2550 m.

**Representative specimens examined.**

**Discussion.** The most distinctive feature of this annual species is the transversely ribbed mericarp, which has thin walls and no longitudinal crest. The eastern limit of *Geranium divaricatum* is not well established, because it is quite difficult to obtain material from Russian herbaria. In Asia, this species reaches the central Siberia (109°E) and the western Himalayas to 76°E. It is known from Sweden by only one collection, which could be an introduction; the nearest locality is in Germany, almost 1000 km southward.

*Geranium trilophum* var. *maculatum* Bornm., Mitth. Thüring. Bot. Vereins 6: 53. 1894. TYPE LOCALITY: “exs. 145... von Buschir”. TYPE: Iran. Faristan, Buschir, 28°58'N, 50°50'E, 17 Mar. 1893, *J. Bornmüller 145* (lectotype, designated by Aedo & al. 2016: 359, W!; isolectotypes, BMI, CAS!, FI!, HBG-517276 image!, K!, LE!, LD!, MPU-018546!, P-00757941!, US image!, WU!).

*Annual herbs*, 19-51 cm tall. *Stem* erect or ascending, leafy, with short retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 1.4-2.1 mm long and, usually, scattered, patent, glandular hairs 0.4-0.5 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite (rarely alternate in middle of shoot, 1-2 nodes); leaf laminas (3.9)4.6-5.1(5.3) cm long, 4.6-6.3 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.58)0.67-0.73], polygonal in outline, base cordate, not coriaceous, with nerves not projected, pilose, with ± appressed, eglandular hairs and plane eglandular hairs on the adaxial surface and ± appressed, eglandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 9.4-11.8 mm wide at the base [ratio segment width at the base/

middle segment length = 0.29-0.38], 9-11(12)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.18-0.20(0.22)]; petioles up to 14 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.6-1.9 mm long and, rarely, patent, glandular hairs 0.2-0.4 mm long; stipules 1.8-4.1 mm long, 0.6-2.2 mm wide, lanceolate, free, papery, green, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary, sometimes grouped at nodes with short or no pedicels [ratio cymule length/leaf length = 0.4-3.9]; peduncles 15-46 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, usually patent, eglandular hairs 1.1-1.6 mm long and patent, glandular hairs 0.4-0.7 mm long; bracteoles 1.8-2.9 mm long, 0.4-0.6 mm wide, lanceolate, whorled; pedicels absent or 4.8-22 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, sometimes patent, eglandular hairs 1-1.6 mm long and patent, glandular hairs 0.3-0.8 mm long. Flowers actinomorphic. *Sepals* 5-6.1(6.2) mm long, 2.5-3.1 mm wide, broadly ovate, smooth, accrescent (6.7-8.9 mm long, 5.5-6.4 mm wide in fruit), nerves 3, mucro 0.5-1.1 mm long [ratio mucro length/sepal length = 0.10-0.22], with ± appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1.1-2.3 mm long and usually patent, glandular hairs 0.5-0.7 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.8)9-9.8(11.2) mm long, 4.9-7.9 mm wide, erect-patent, rounded, without claw, purple with a dark basal spot, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.3 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.7-4.4 mm long, lanceolate, black except the base, glabrous; anthers 1.2-1.3 mm long, purple. *Nectaries* 5, hemispheric, glabrous. *Gy-*

*noecium* 4-6.2 mm long, dark purple. *Fruit* (17.8)18.4-20.8(21.4) mm long, erect, discharge of carpel-projection type, operative; *mericarps* 5-5.8(6.5) mm long, 2.4-3.4 mm wide, without a strand of fibers, not compressed at the apex, with two longitudinal toothed wings bent dorsally to form a trough-like structure and with an

evident ridge in the middle, protruding beyond the trough-like structure, without horns, without basal beak, without a basal callus, without a basal prong, brown, with appressed, eglandular hairs 0.1-0.2 mm long; *rostrum* 10.4-14.2 mm long, without a narrowed apex, twisted distally, with patent, eglandular hairs 0.3-0.8 mm long

and, usually, a group of patent, eglandular hairs 0.6-1.1 mm long towards the apex; *stigmatic remnants* 0.3-0.6 mm long, with 5 glabrous lobes. *Seeds* 2.2-2.7 mm long, 1.1-1.3 mm wide, smooth, uniformly colored, brownish red, glabrous. *Cotyledons* with entire margin. Fig. 716.

*Pollen*. *Erodium*-type (Aedo & al. 2016: 356).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from March to April.

*Distribution*. This species ranges from southern Iran to Oman (Fig. 717).

*Habitat*. Open scrublands, grassland plains, cliffs or tops of escarpments, under shaded bushes and disturbed areas; 0-2300 m.

*Additional specimens examined. Iran.*

**Discussion.** *Geranium trilophum* is erect or ascending, with basal leaves in a deciduous rosette and cauline leaves opposite, rarely alternate towards the basal third of the stem, and a monochasial inflorescence. It is easily identified by its purple petals with a dark basal spot, its accrescent and very wide sepals and its singular mericarps. Mericarps of *G. trilophum* have two longitudinal toothed wings bent dorsally to form a trough-like structure with an evident ridge in the middle, protruding from the trough-like structure. The indumentum of *G. trilophum* is composed of short,  $\pm$  uncinat, eglandular hairs on stems, leaves and inflorescence, and usually glandular, patent hairs and long, eglandular, patent hairs. Some specimens of *G. trilophum* have 2-flowered cymules with well-developed peduncle and pedicels in some nodes and cymules or aggregates of cymules without pedicels in other nodes. In other specimens only the second type of cymule is found. According to Schönbeck-Temesy (1970) *G. trilophum* frequently produces cleistogamous flowers. *Geranium trilophum* is an endemic plant of the north side of the Persian Gulf. Knuth (1912) also included plants from Yemen and adjacent areas of northeast Africa in *G. trilophum*. Schönbeck-Temesy (1970), Kokwaro (1971a), Thulin (1993), Alfathan & Thomas (2001), and Patzelt (2007) concurred with Kunth. However, plants from those

areas are easily distinguished from *G. trilophum* by their shorter petals and sepals. Additionally they have a mericarp with a much smaller ridge which is covered by the trough-like structure. Those plants were described by Deflers (1889) as *G. yemense*, a name that has been misapplied frequently (see discussion under *G. yemense* and *G. biuncinatum*).

*Annual herbs*, 8-62 cm tall. *Stem* erect or ascending, leafy, with short retrorse, not appressed, eglandular hairs 0.1-0.3 mm long (rarely also, patent, eglandular hairs 1.5-1.7 mm long) and, sometimes, scattered, patent, glandular hairs 0.4-0.9 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite (rarely alternate in middle of shoot, 1-2 nodes); leaf laminas (2.1)3.4-4.9(6.4) cm long, 2.8-7.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.59)0.66-0.77(0.86)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane eglandular hairs on the adaxial surface and  $\pm$  appressed, eglandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 6-14.9 mm wide at the

base [ratio segment width at the base/middle segment length = (0.27)0.29-0.37(0.39)], (7)8-17(26)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.22-0.28(0.34)]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, sometimes also patent, eglandular hairs 1-2.9 mm long and, rarely, patent, glandular hairs 0.5-0.7 mm long; stipules 1.7-3.2 mm long, 0.5-1.9 mm wide, lanceolate, free, papery, green, with eglandular hairs on abaxial surface and on the margin, usually glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary, sometimes grouped at nodes with short or no pedicels [ratio cymule length/leaf length = 0.2-5]; peduncles 3-25 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long and, usually patent, glandular hairs 0.4-0.7 mm long; bracteoles 1.7-2.9 mm long, 0.5-0.7 mm wide, lanceolate, whorled; pedicels absent or 3.9-23.7 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, sometimes patent, eglandular hairs 1-1.2 mm long and, usually, patent, glandular hairs 0.3-0.6 mm long. Flowers actinomorphic. *Sepals* (3.3)3.6-4.2(4.8) mm long, 1.6-2.7 mm wide, broadly ovate, smooth, accrescent (5.2-7.5 mm long, 3.3-5.1 mm wide in fruit), nerves 3, mucro 0.5-1.3 mm long [ratio mucro length/sepal length = 0.12-0.40], with  $\pm$  appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1.4-2.9 mm long and usually patent, glandular hairs 0.4-1 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.8)6.1-8.1(8.7) mm long, 3.1-5.2 mm wide, erect-patent, rounded, without claw, purple with a dark basal spot, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.1-3.6 mm long, lanceolate, black except the base, glabrous or with scattered cilia 0.1-0.2 mm long

on the margin; anthers 0.7-1.1 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoeceum* 2.6-3.7 mm long, dark purple. *Fruit* (14.1)15.9-17.4(18.6) mm long, erect, discharge of carpel-projection type, operative; mericarps 3.7-4.6(4.8) mm long, 1.9-3.4 mm wide, without a strand of fibers, not compressed at the apex, with two longitudinal toothed wings

bent dorsally to form a trough-like structure and with a small ridge in the middle, inside the trough-like structure, without horns, without basal beak, without a basal callus, without a basal prong, brown, with appressed, eglandular hairs 0.1-0.2 mm long; rostrum 8.8-12.6 mm long, without a narrowed apex, twisted distally, with erect-patent, eglandular hairs 0.1-0.4

mm long; stigmatic remnants 0.2-0.6 mm long, with 5 glabrous lobes. *Seeds* 2.1-2.4 mm long, 1-1.2 mm wide, smooth, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 718.

*Pollen*. *Erodium*-type (Aedo & al. 2016: 356).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to May.

*Distribution*. This species ranges through Jordan, eastern Egypt and Sudan, western Yemen, Socotra, Djibouti, Eritrea, northern Ethiopia and Somalia (Fig. 719).

*Habitat*. In shade of small trees on limestone escarpments, coffee terraces and other cultivated areas; 600-2850 m.

**Discussion.** *Geranium yemense* shares with *G. trilophum* a similar inflorescence structure, annual habit, indumentum, accrescent sepals, and petal color. However, in *G. yemense* the sepals, the petals, the fruits, and the seeds are shorter than in *G. trilophum*. Additionally, *G. yemense* has leaves with more lobes per segment, but with a substantial overlap. The mericarp of *G. yemense* has a small ridge which is covered by the trough-like structure, while *G. trilophum* has an evident ridge protruding beyond the trough-like structure. The species are separated by more than 1000 km. Knuth (1912) misapplied the name *G. yemense* to the plants here recognized as *G. biuncinatum*, as noted Kokwaro (1971a). Knuth (1912) used 'Valvulae apice unguibus duobus ornatae' to key out *G. yemense*; however this is an unequivocal feature of *G. biuncinatum*. Additionally, he included both specimens with horns and without horns in the material

studied of *G. yemense* (i.e. *Deflers 296*, which is the type of *G. yemense*). At the same time Knuth (1912) included within *G. trilophum* specimens from Yemen and adjacent areas that should be considered to be *G. yemense*. Kokwaro (1971a), rightly separated specimens with horns on the mericarp as *G. biuncinatum*, but considered *G. yemense* to be a synonym of *G. trilophum*. Zohary (1972) recorded *G. trilophum* from Jordan (Moav and Edom regions). Considering that these areas are close to the area of *G. yemense* in Jordan, it seems feasible that such records should be attributed to *G. yemense*. Such is the case of the Egyptian specimen *Täckholm s.n.* (S) that Täckholm & Chrtek (1968: 140) considered as *G. trilophum*, and probably that of the remaining specimens cited by these authors.

*Geranium omphalodeum* was described by Lange (1866) from seeds of unknown origin cultivated at the Copenhagen Botanic Garden. Knuth (1912) included this name under the synonymy of *G. ocellatum*. Laundon (1961) suggested that *G. omphalodeum* is a synonym of *G. trilophum* while Kokwaro (1971a) did not address this problem. Yeo (2002a) tentatively accepted this taxon considering that its recognition might lead to its re-discovery in nature. The last author considered that *G. omphalodeum* can be distinguished from *G. trilophum* by its small mericarps and its deeply dissected leaves. It should be noted that Yeo did not differentiate *G. yemense* from *G. trilophum*, even though the mericarps of *G. yemense* are shorter than those of *G. trilophum*. The type of *G. omphalodeum* fits very well with *G. yemense*, although the leaves are a bit more deeply divided. Consequently, it has been included in the synonymy of *G. yemense*.

**284. *Geranium biuncinatum*** Kokwaro, Webbia 25(2): 639. 1971. TYPE LOCALITY: "Somali republic, Northern Region, Sugli Al Hills at 4700-6000 ft,

Northern Region, Sugli Al Hills, 10°58'N, 48°53'E, 15 Nov. 1929, C.L. Collenette 289 (holotype, K-000417204!).

*Annual herbs*, 12-62 cm tall. *Stem* erect or ascending, leafy, with short retrorse, not appressed, eglandular hairs 0.2-0.3 mm long (sometimes also patent, eglandular hairs 1.2-1.9 mm long) and scattered, patent, glandular hairs 0.4-0.6 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminas (2.6)4-4.5(5.8) cm long, 3-6.8 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.68)0.72-0.77(0.78)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± appressed, eglandular hairs and plane eglandular hairs on the adaxial surface and ± appressed, eglandular hairs and scattered glandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 6.2-10.9 mm wide at the base [ratio segment width at the base/middle segment length = (0.23)0.26-0.29(0.33)], (5)10-15(18)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.16)0.22-0.26(0.30)]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, not appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1.1-1.5 mm long and, usually, patent, glandular hairs 0.4-0.7 mm long; stipules 1.4-3.1 mm long, 0.6-1.6 mm wide, lanceolate, free, papery, green, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary, sometimes grouped at nodes with short or no pedicels [ratio cymule length/leaf

length = 0.2-0.9(2)]; peduncles 10-27 mm long, with retrorse, not appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1-1.2 mm long and patent, glandular hairs 0.3-0.7 mm long; bracteoles 1.3-2.6 mm long, 0.5-0.9 mm wide, lanceolate, whorled; pedicels absent or 3-19 mm long, with retrorse, not appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1-1.2 mm long and, usually, patent, glandular hairs 0.3-0.6 mm long. Flowers actinomorphic. *Sepals* 4.6-5.1(6) mm long, 2.4-3.4 mm wide, broadly ovate, smooth, accrescent (6.2-7.9 mm long, 3.7-5.5 mm wide in fruit), nerves 3, mucro 0.5-0.9 mm long [ratio mucro length/sepal length = 0.10-0.17], with  $\pm$  appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1-1.6 mm long and usually patent, glandular hairs 0.5-0.8 mm long on the abaxial surface, glabrous adaxially. *Petals* 7.5-9.3 mm long, 4.9-5.6 mm wide, erect-patent, rounded, without claw, purple with a dark basal spot, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.1-3.6 mm long, lanceolate, black except the base, glabrous or with scattered cilia 0.1-0.2 mm long on the margin; anthers 0.8-1 mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 2.7-3.9 mm long, dark purple. *Fruit* (15.7)17-19.5(20.3) mm long, erect, discharge of carpel-projection type, operative; mericarps (4.9)5.4-6.8(7.1) mm long, 2.5-3.4 mm wide, without a strand of fibers, not compressed at the apex, with two longitudinal toothed wings bent dorsally to form a trough-like structure, continued at the top into a hook 3.9-4.8 mm long on either side looking like a pair of horns, and with a small ridge in the middle, inside the trough-like structure, without basal beak, without a basal callus, without a basal prong, brown, with appressed, eglandular hairs 0.1-0.2 mm long; rostrum 9.5-12.3 mm long, without a

narrowed apex, twisted distally, with antrorse, not appressed, eglandular hairs 0.1-0.3 mm long and usually a group of patent, eglandular hairs 0.8-1.1 mm long towards the apex; stigmatic remnants 0.2-0.4 mm long, with 5 glabrous lobes. *Seeds* 2-2.5 mm long, 0.9-1.1 mm wide, smooth, uniformly colored, brownish red, gla-

brous. Cotyledons with entire margin. Figs. 720, 721.

*Pollen*. *Erodium*-type (Aedo & al. 2016: 356).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from February to July.

*Distribution*. This species ranges from northeastern Oman, through

**Discussion.** *Geranium biuncinatum* is an annual with opposite leaves, more or less covered by eglandular and usually glandular hairs. It is easily identified by its purple petals with a dark basal spot, its accrescent and very wide sepals and its singular mericarps. Mericarps of *G. biuncinatum* have toothed wings continuing in a pair of recurved horns which is a unique condition in the genus. *Geranium trilophum* and *G. yemense* have similar mericarps but without horns. The indumentum of *G. biuncinatum* is composed of short,  $\pm$  uncinat, eglandular hairs on stems, leaves and inflorescence, and sometimes glandular hairs also. In some specimens, long, patent hairs are mainly on the sepals and cymules. The sepals grow during mericarp maturation to cover the mericarps, except the horns. Sepals in fruit are very unequal, the two inner being smaller. The measurements in the descriptions correspond to the external sepals. *Geranium biuncinatum* shares with *G. trilophum* and *G. yemense* the previously mentioned sepal features. Sepals and petals of *G. biuncinatum* are intermediate in length between *G. trilophum* and *G. yemense*. Meri-

carps, excluding the horns, are longer than in *G. yemense* and similar to *G. trilophum*. Plants grown at Madrid Botanical Garden during spring of 2001 from seeds kindly provided by P. Yeo (*Woods* 3126), showed cleistogamous flowers (vouchers: MA-648734, MA-657456). Those flowers never opened but matured into fertile fruits. Knuth (1912) misapplied the name *G. yemense* to the plants here recognized as *G. biuncinatum* as was noted by Kokwaro (1971a) (see the discussion under *G. yemense*). Chrtek (1968) proposed the genus *Geraniopsis* to segregate the species with mericarps with two longitudinal toothed wings bent dorsally to form a trough-like structure. Yeo (1973a) concurs with Schönbeck-Temesy (1970) in considering *Geraniopsis* unjustified. *Geranium biuncinatum* has been reported from Saudi Arabia (Alfarhan & Thomas 2001). Unfortunately, I did not see the voucher for this record. Reports for Ethiopia (Kokwaro 1971a) probably refer to Eritrea (Gilbert & Voster 2000).

**Discussion.** *Geranium favosum* is an annual herb, erect or ascending, with basal leaves in a deciduous rosette and a monochasial inflorescence. The leaves of the distal part of the stem and inflorescence are opposite while

those of the middle and base of the stem are alternate. As in the remaining species of the section, the indumentum of *G. favosum* is composed of short, ± uncinuate, eglandular hairs on stems, leaves and inflorescence, and usually glandular, patent hairs. Long eglandular hairs also appear in many individuals. Cymules of *G.*

*favosum* are usually 2-flowered, with well-developed peduncle and pedicels, but in some nodes umbel-like aggregates with short or absent pedicels appear. *Geranium favosum* is quite similar to *G. mascatense* in general appearance. Both species share alternate leaves on the middle and base of the stem and a mericarp with almost the same ornamentation. The mericarps are transversely wrinkled, with prominent ribs, separated by furrows ca. 0.3 mm deep, 0.3-0.5 mm wide, and usually with transverse ribs connecting the main ribs. In both species, small, appressed hairs occur mainly on the ribs. The mericarps of *G. favosum* are smaller than those of *G. mascatense* usually have fewer transverse ribs, but there is a significant overlap in these features. The mericarps of *G. brevipes* resemble those of *G. favosum* but have slightly prominent ribs and, consequently shallow furrows ca. 0.1 mm deep. Petals of *G. favosum* are consistently without a dark basal spot, while in *G. brevipes* and *G. mascatense* this spot has been observed in most individuals. In contrast, in all species of the section, including *G. favosum*, the staminal filaments are blackish except for the base and the stigma is dark purplish. The leaves of *G. favosum* are quite different from those of the remaining species of the section because they are deeply divided: the middle segment has a narrower base,

Fig. 724. Distribution of *Geranium favosum*.

and the main sinus and the secondary sinus of the middle segment are deeper. Kokwaro (1971a) reported *G. favosum* from Djibouti on the basis of three specimens. Two of them (Denis 184, P; De la Rue s.n., P) are *G. mascatense* while Anla 90 (K) has not been examined. Thus, the presence of *G. favosum* in Djibouti should be confirmed.

*Annual herbs*, 12-58 cm tall. *Stem* erect or ascending, leafy, with short retrorse, not appressed, eglandular hairs 0.2-0.6 mm long, patent, eglandular hairs 1.1-3 mm long and, usually, scattered, patent, glandular hairs 0.2-0.6 mm long. *Basal leaves* in a deciduous rosette, cauline leaves alternate and upper opposite; leaf laminas (2.2)2.5-5.2(6.5) cm long, 2.6-7.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.63)0.66-0.74(0.81)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane eglandular hairs on the adaxial surface and  $\pm$  appressed, eglandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 4.7-13.4 mm wide at the base [ratio segment width at the base/

middle segment length = (0.24)0.30-0.35(0.41)], (6)7-15(22)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.13)0.18-0.24(0.29)]; petioles up to 14 cm long, without abscission zone, terete, not swollen, not deflexed in age, with short retrorse, not appressed, eglandular hairs 0.2-0.4 mm long, usually, patent, eglandular hairs 1.1-2.1 mm long and, usually, patent, glandular hairs 0.2-0.5 mm long; stipules 1.1-3 mm long, 0.4-1.3 mm wide, lanceolate, free, papery, green, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary, sometimes grouped at nodes with short or no pedicels [ratio cymule length/leaf length = 0.2-5.3]; peduncles 1-21 mm long, with retrorse, not appressed, eglandular hairs 0.2-0.5 mm long, rarely patent, eglandular hairs 1.3-1.5 mm long and, usually, patent, glandular hairs 0.2-0.6 mm long; bracteoles 1.2-2.7 mm long, 0.3-0.7 mm wide, lanceolate, whorled; pedicels absent or 4-21.3 mm long, with retrorse, not appressed eglandular hairs 0.2-0.7 mm long, rarely patent, eglandular hairs 1.4-2.2 mm long and, usually, patent, glandular hairs 0.3-0.7 mm long. Flowers actinomorphic. *Sepals* (3.4)3.5-4(4.1) mm long, 1.6-2.3 mm wide, ovate, smooth, accrescent (4.3-6 mm long, 1.9-5.4 mm wide in fruit), nerves 3, mucro 0.3-1.5 mm long [ratio mucro length/sepal length = 0.14-0.22], with  $\pm$  appressed, eglandular hairs 0.2-0.3 mm long, patent, eglandular hairs 1.3-2.4 mm long and patent, glandular hairs 0.3-0.8 mm long on the abaxial surface, glabrous adaxially. *Petals* (4.4)6.3-7.5(8.9) mm long, 1.8-5.6 mm wide, erect-patent, rounded, without claw, purple, usually with a dark basal spot, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.4-3.8 mm long, lanceolate, black except the base, glabrous; anthers 0.8-1.2 mm long, purple. Nectaries 5, hemispheric, gla-

brous. *Gynoecium* 2.6-4.3 mm long, dark purple. *Fruit* (9.3)11.8-14(14.6) mm long, erect, discharge of carpel-projection type, operative; mericarps (2.5)2.7-3.5 mm long, 1.1-1.8 mm wide, without a strand of fibers, not compressed at the apex, transversely wrinkled, with 4-6 prominent ribs, separated by furrows ca. 0.3 mm deep, 0.3-0.5 mm wide, without wings, without basal beak, without a basal callus, without a basal prong, brown or grey, with appressed, eglandular hairs 0.1 mm long, mainly on the ribs; rostrum 5.8-10.7 mm long, without a narrowed apex, twisted distally, with erect-patent, eglandular hairs 0.1-0.4 mm long; stigmatic remnants 0.2-0.6 mm long, with 5 glabrous lobes. *Seeds* 1.8-2.6 mm long, 0.8-1.4 mm wide, smooth, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 725, 726.

*Pollen*. *Erodium*-type (Aedo & al. 2016: 356).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from January to September.

*Distribution*. This species ranges from Israel, Iran, Oman and Yemen to Egypt, Sudan, Djibouti, Eritrea and Somalia (Fig. 727).

*Habitat*. Shaded areas, rocky slopes with large boulders, cliff and shady banks, forest edges and cultivated fields; 50-2000 m.

*Additional specimens examined*. **Djibouti**. OBOCK: cote française des Somalis, monts Mabila, piste de Obock à Sismo, 11°56'N, 43°2'E, 18 Feb. 1938, Aubert de la Rue s.n. (P). **Discussion.** *Geranium mascatense* is quite similar to *G. favosum* in general appearance. Both species share a similar mericarp and alternate leaves on the base of the stem. *Geranium mascatense*, however, can be easily distinguished by its less divided leaves and its petals which usually have a basal spot. *Geranium mascatense* has been sometimes confused with *G. brevipes*, a partially sympatric species. Both share leaves of similar appearance and petals with a basal dark spot. *Geranium mascatense* is recognized by its distinctive mericarps with strongly prominent ribs and, consequently, deep furrows (usually ca. 0.3 mm deep). According to Schönbeck-Temesy (1970: 34) *G. mascatense* frequently produces cleistogamous flowers. Knuth (1912) included *G. mascatense* under *G. ocellatum*. In contrast, *G. mascatense* has been widely accepted in the regional literature as a distinct species (Alfarhan & Thomas 2001; Gilbert &

Voster 2000; Kokwaro 1971a; Laundon 1961; Schönbeck-Temesy 1970). Nasir (1983) recorded *G. mascatense* from southern Pakistan and Alfarhan & Thomas (2001) from southwestern Saudi Arabia. Unfortunately I did not see vouchers for these reports.

**Discussion.** *Geranium ocellatum* is an annual herb, erect or ascending, with basal leaves in a ± persistent rosette, usually opposite on the stem, and a monochasial inflorescence. It is easily identified by its purple petals with a dark basal spot and its glabrous mericarps, transversely wrinkled with

8-14 ribs. The ribs are slightly prominent, usually parallel, sometimes forked, and separated by a shallow sinus 0.2-0.3 mm wide. There are no transverse veins or ribs connecting the main ribs. The indumentum of *G. ocellatum* is composed of short, ± uncinata, eglandular hairs on stems, leaves and inflorescence, and usually glandular, patent hairs. Long eglandular hairs also appear in many individuals. Cymules of *G. ocellatum* are usually 2-flowered, with well-developed peduncles and pedicels, but in some nodes umbel-like aggregates with short or absent pedicels appear. Knuth (1912: 62) had a broad concept of *G. ocellatum* that included plants from the Himalayas, Arabian Peninsula and Africa. His opinion was shared by Laundon (1961: 68) and Kokwaro (1971a: 643). In contrast, Gilbert & Voster (2000: 367) and Yeo (2002a: 165) indicated that there may be differences between the plants from the Himalayas and those from Arabia and Africa. I followed the criteria of the latter authors and separated the plants from Arabia and Africa as a different species, under the name *G. brevipes*. Mericarps of *G. brevipes* have appressed, eglandular hairs 0.1 mm long, mainly on the ribs. Additionally, the ribs are fewer (usually 4-6), separated by wider sinuses (0.3-0.4 mm wide) and connected by veins or small ribs. The two species are allopatric and their ranges are separated by some 3,000 km. According to Yeo (2002a: 165) *G. ocellatum* frequently produces cleistogamous flowers. These cleistogamic forms have been recently described as *G. indicum* (Hurrah & al. 2021).

*Annual herbs*, 16-62 cm tall. *Stem* erect or ascending, leafy, without vegetative stems, with short retrorse, not appressed, eglandular hairs 0.1-0.4 mm long, usually, patent, eglandular hairs 1.4-2.8 mm long and, usually, scattered, patent, glandular hairs 0.3-0.9 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite (sometimes alternate in middle of shoot, 1-2 nodes); leaf laminae (1.4)2.7-4.6(6.2) cm long, 1.7-7.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.63)0.66-0.74(0.80)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane eglandular hairs on the adaxial surface and  $\pm$  appressed, eglandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 2.7-14.9 mm wide at the base [ratio segment width at the base/middle segment length = (0.20)0.28-0.34(0.42)], (7)10-15(20)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.16)0.19-0.24(0.30)]; petioles up to 16 cm long, without abscission zone, terete, not swollen, not deflexed in age, with retrorse, not appressed, eglandular

hairs 0.1-0.4 mm long, usually patent, eglandular hairs 1.1-2.5 mm long and, usually, patent, glandular hairs 0.3-0.8 mm long; stipules 1.8-4.3 mm long, 0.6-1.6 mm wide, lanceolate, free, papery, green, with eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (1)2-flowered, solitary, sometimes grouped at nodes with short or no pedicels [ratio cymule length/leaf length = 0.1-5.3]; peduncles 5.9-32 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, sometimes patent, eglandular hairs 1-2.1 mm long and, usually, patent, glandular hairs 0.2-0.9 mm long; bracteoles 1.7-4.4 mm long, 0.4-0.8 mm wide, lanceolate, whorled; pedicels absent or 3.3-18 mm long, with retrorse, not appressed, eglandular hairs 0.1-0.3 mm long, sometimes patent, eglandular hairs 1-2.1 mm long and patent, glandular hairs 0.3-1 mm long. Flowers actinomorphic. *Sepals* 3.5-4.2(4.9) mm long, 1.4-2.2 mm wide, ovate, smooth, slightly accrescent (4.4-5.7 mm long, 2-3.7 mm wide in fruit), nerves 3, mucro 0.4-1.2 mm long [ratio mucro length/sepal length = 0.13-0.29], with  $\pm$  appressed, eglandular hairs 0.2-0.3 mm long, sometimes also patent, eglandular hairs 1.4-2.9 mm long and patent, glandular hairs 0.3-0.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (5.8)6.3-7.1(8.8) mm long, 2.5-5.1 mm wide, erect-patent, rounded, without claw, purple, usually with a dark basal spot, glabrous on both surfaces, ciliate on the basal margin, with hairs 0.1-0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.5-3.8 mm long, lanceolate, black except the base, glabrous; anthers 0.8-1.1 mm long, dark purple. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 2.5-3.8 mm long, dark purple. *Fruit* (10.4)12-14.2(14.5) mm long, erect, discharge of carpel-projection type, operative; mericarps (2)2.2-2.8(3) mm long, 1.1-1.6 mm wide, without a strand of fibers, not compressed at the apex, transversely

wrinkled, with 4-6 slightly prominent ribs, separated 0.3-0.4 mm, without wings, without basal beak, without a basal callus, without a basal prong, brown or glaucous, with appressed, eglandular hairs 0.1 mm long, mainly on the ribs; rostrum 7.5-10.8 mm long, without a narrowed apex, twisted distally, with erect-patent, eglandular hairs 0.1-0.3 mm long; stigmatic remnants 0.2-0.5 mm long, with 5 glabrous lobes. *Seeds* 1.4-2.4 mm long, 0.8-1.3 mm wide, smooth, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Fig. 730.

*Pollen*. *Erodium*-type (Aedo & al. 2016: 356).

*Chromosome number*.  $2n = 56$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges from southwestern Saudi Arabia and Yemen, through Djibouti and Cameroon to Angola and Zimbabwe (Fig. 731).

*Habitat*. Shaded areas, grassy slopes, meadows, slopes of ravines with scattered boulders and bushes, rock ledges, open bushlands, forest edges, walls and cultivated fields; 1200-3000 m.

**Discussion.** *Geranium brevipes* is quite similar to *G. ocellatum* in general appearance. Both species are annual herbs, with cauline, usually opposite leaves, and they share a monochasial inflorescence and purple petals with a dark basal spot. However, *G. brevipes* can be easily distinguished by its mericarps which have short and appressed hairs (glabrous in *G. ocellatum*), and fewer ribs (see more details under *G. ocellatum*). Additionally, *G. brevipes* is more robust and has longer leaves, accrescent sepals with longer mucro and longer mericarps and seeds than *G. ocellatum*. The leaves of *G. brevipes* are usually shallowly divided. However, three collections appear with deeply divided leaves: *Chapman 1239* (NY) from Malawi, *Dandy 131* (BM) from Sudan, and *Gilli 261* from Tanzania. Otherwise, they fall well within the range of variability of *G. brevipes*. According to Kers (1971) *G. brevipes* (sub *G. ocellatum*) frequently shows cleistogamous flowers. *Geranium brevipes* occurs from Yemen and Saudi Arabia to Zimbabwe, through the highlands of East Africa. It is also present on the plateaus of Angola and in the Camer-

oon mountains. Since Knuth (1912), it has been considered that these plants should be included in *G. ocellatum*, a Himalayan species, sometimes at varietal rank. However, the indumentum and ornamentation of the mericarp are consistent in plants from Arabian Peninsula and Africa, but are not found in the Himalayan individuals. Consequently, this endemic form deserves specific status, for which two specific epithets were available, *G. brevipes* being the oldest.

---

**Ivd. Geranium sect. Polyantha** Reiche in Engl. & Prantl, Nat. Pflanzenfam. 3(4): 8. 1890. TYPE: *Geranium polyanthes* Edgew. & Hook. f. (art. 10.8).

*Geranium* sect. *Strigosa* C.C. Huang & L.R. Xu, Fl. Reipubl. Pop. Sin. 43(1): 47. 1998. TYPE: *Geranium strictipes* R. Knuth (designated by Xu & al. 1998: 47).

*Perennial herbs. Flowers* actinomorphic. *Petals* usually rounded, without claw. *Pollen* of *Erodium*-type. *Fruit* of carpel-projection type, operative; mericarps reticulate; rostrum not twisted. *Cotyledons* with entire margins.

*Geranium hispidissimum*, *G. strictipes*, and *G. wardii* share an inflorescence with a dichasial structure and opposite leaves. In contrast, the group comprising *G. polyanthes*, *G. umbelliforme*, and *G. moupinense* has a monochasial inflorescence and alternate leaves (at least in the middle of the shoot). *Geranium nakaoanum* is somewhat intermediate, having a monochasial inflorescence but leaves usually opposite. This species is also the only one in the section showing some other features, e.g., usually 1-flowered cymules, scarce indumentum, and staminal filament shape.

*Geranium strigosum* var. *platylobum* Franch., Pl. Delavay.: 113. 1889. *Geranium platylobum* (Franch.) R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 183. 1912. TYPE LOCALITY: "In silvis montis Che-tcho-tze, supra Tapin-tze. alt. 2000 m.; 6 aug. 1887 (Delavay, n. 2756)". TYPE: China. Yunnan, montis Che-tcho-tze, supra Tapin-tze, 25°34'N, 100°14'E, 6 Aug. 1887, *P.J. Delavay 2756* (lectotype, designated by Kunth 1912: 183, P-00712095!; isolectotype, K-000380192!).

*Perennial herbs*, 16-72 cm tall. *Rootstock* 6-16 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.5-3.3 mm long (sometimes lacking) and patent, glandular hairs 0.3-3.5 mm long. *Basal leaves* in a ± persistent rosette, cauline leaves opposite; leaf laminas (2.4)3.5-4.4(5.3) cm long, 3.2-8.4 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.55)0.68-0.77(0.81)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± appressed, eglandular hairs and plane glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 4.8-11.7 mm wide at the base [ratio segment width at the base/middle segment length = (0.23)0.27-0.38(0.48)], 9-16-lobed in distal half [ratio secondary sinus length/middle segment length = (0.14)0.16-0.24(0.28)]; petioles up to 15 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinete, eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs

0.4-3.1 mm long (sometimes lacking) and patent, glandular hairs 0.4-3.2 mm long; stipules 3.9-13.2 mm long, 0.9-3.1 mm wide, lanceolate, free, herbaceous, green, with scattered, eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule

length/leaf length = 1.1-3.9]; peduncles (11)69-129(145) mm long, with uncinete eglandular hairs 0.1-0.3 mm long, patent, eglandular hairs 0.5-3.2 mm long (sometimes lacking) and patent, glandular hairs 1.2-2.4 mm long; bracteoles 4.5-6.6 mm long, 0.5-1.1 mm wide, lanceolate, whorled; pedicels (8.1)0.3-22(31.8) mm long, with uncinete, retrorse eglandular

hairs 0.1-0.3 mm long, patent, eglandular hairs 0.2-2.2 mm long (sometimes lacking) and patent, glandular hairs 0.6-2 mm long. Flowers actinomorphic. *Sepals* (4.9)5.2-6.4(7.3) mm long, 2.1-3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.8-2.4 mm long [ratio mucro length/sepal length = 0.17-0.35], with  $\pm$  patent, eglandular hairs 0.1-0.5 mm long and patent, glandular hairs 1-3.4 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.6)9-9.8(10.6) mm long, 3.9-7.3 mm wide, erect-patent, rounded, without claw, white to purple, hairy on the base of the adaxial surface, usually glabrous on the abaxial surface, ciliate on the basal margin, with hairs 0.4-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.8-5.1 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.2-0.9 mm long; anthers 1.2-1.7 mm long, unknown color. *Nectaries* 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 3.1-5.9 mm long, pink. *Fruit* 23-28 mm long, erect, discharge of carpel-projection type, operative; mericarps 3.7-4.7 mm long, 1.2-1.8 mm wide, without a strand of fibers, not compressed at the apex, reticulate, without basal beak, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long; rostrum 16-20 mm long, without a narrowed apex or with a narrowed apex 0.5-1 mm long, not twisted, with patent, eglandular hairs 0.1-0.2 mm long and patent, scattered, glandular hairs 0.1-0.7 mm long; stigmatic remnants 1.5-2.4 mm long, with 5 glabrous lobes. *Seeds* 2.2-3.3 mm long, 1-1.5 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 732.

*Pollen*. *Erodium*-type (Aedo 2016: 615).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from May to November.

*Distribution*. This species ranges from Sichuan to Yunnan, in southern China (Fig. 733).

**Discussion.** *Geranium hispidissimum* shares with *G. strictipes* an erect habit, stout, vertical rootstock, opposite leaves, and inflorescence in dichasial cyme with monochasial branches. *Geranium hispidissimum* is, however, easy to identify from its less deeply divided leaves and its shorter petals. It also has shorter sepals, staminal filaments, anthers, fruit, rostrum narrowed apex and seeds. These features overlap to some degree. The indumentum of *G. hispidissimum* is also variable but is usually denser than in *G. strictipes*, especially on the leaves. *Geranium hispidissimum* and *G. strictipes* share with *G. moupinense* sepals with longer mucro. In these species the sepal mucro is green; in the remaining species of the section it is purple. The ranges of *G. hispidissimum* and *G. strigosum* overlap, and they occur sometimes in the same locality. Knuth (1912) recognized *G. platylobum* but did not indicate any difference from *G. strictipes* to key it out. According to Yeo (1992), *G. platylobum* is an extreme case with unusual rounded leaf segments and obtuse lobes. The study of the type material shows that *G. platylobum* has short petals and leaves that are not as deeply divided as in *G. hispidissimum*.

**290. *Geranium moupinense* Franch.,** Nouv. Arch. Mus. Hist. Nat. ser. 2, 8(2): 208. 1885. TYPE LOCALITY: "Moupine, in locis umbrosis. Jun. 1869". TYPE: China. Sichuan, Moupine, 30°23'N, 102°50'E, June 1869, A. *David s.n.* (lectotype, designated by Aedo 2016: 620, P!; isotype, MA-628480!).

(holotype, SZ image!; the type was originally at CDCM).

**Perennial herbs**, 12-25 cm tall. **Rootstock** 3-5 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. **Stem** erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with uncinat, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 0.7-1.1 mm long. **Basal leaves** in a  $\pm$  persistent rosette, cauline leaves alternate; leaf laminae 3.6-5.8 cm long, 4.6-5.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.76-0.81], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 3.7-6.9 mm wide at the base [ratio segment width at the base/middle segment length = 0.26-0.35], 3-7-lobed in distal half [ratio secondary sinus length/middle segment length = 0.14-0.18]; petioles up to 12 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinat, eglandular hairs 0.1-0.2 mm long and patent, glandular hairs 0.8-1.1 mm long; stipules 4.9-5.1 mm long, 1.5-1.6 mm wide, broadly lanceolate, free, papery, brown, with scattered, eglandular hairs on abaxial surface and on the margin, glabrous adaxially. **Inflorescence** a monochasial cyme; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2.3-2.9]; peduncles 48-72 mm long, with uncinat, retrorse, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.8-1.6 mm long; bracteoles 5-6.6 mm long, 1-1.2 mm wide, lanceolate, whorled; pedicels 25-28 mm long, with uncinat, retrorse, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.7-1.1 mm long. Flowers actinomorphic. **Sepals** 7.9-8.9 mm long, 1.8-4.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.7-1.8 mm long [ra-

tio mucro length/sepal length = 0.19-0.22], with  $\pm$  patent, eglandular hairs 0.1-0.3 mm long and patent, glandular hairs 1.4-1.8 mm long on the abaxial surface, glabrous adaxially. *Petals* 12-12.2 mm long, 5.3-7.7 mm wide, erect-patent, rounded, with-

out claw, purple, hairy on the base of both surfaces, ciliate on the basal margin, with hairs ca. 0.2 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.7-4 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half,

with hairs 0.4-1 mm long; anthers 1.6-1.7 mm long, unknown color. Nectaries 5, hemispheric, with a tuft of hairs at the top, dorsally glabrous. *Gynoecium* 5-5.5 mm long, unknown color. *Fruit* 20-23 mm long, erect, discharge of carpel-projection type, operative; mericarps 3-3.2 mm long, 1-1.1 mm wide, without a strand of fibers, not compressed at the apex, reticulate, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long; rostrum 16.5 mm long, with a narrowed apex 1.5-1.7 mm long, not twisted, with patent, eglandular hairs 0.2-0.3 mm long; stigmatic remnants 1.8-2 mm long, with 5 glabrous lobes. *Seeds* 2-2.1 mm long, 0.9-1 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 734.

*Pollen*. *Erodium*-type (Aedo 2016: 614).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in June.

*Distribution*. This species is endemic to Sichuan, in southwestern China (Fig. 735).

*Habitat*. Shaded areas; unknown altitude.

*Discussion*. *Geranium moupinense* is an erect perennial herb that shares the feature of alternating leaves on the stem with *G. polyanthes* and *G.*

J.L. Cantillo, 2016

Fig. 734. *Geranium moupinense*. a. Habit. b. Leaf. c. Petiole indumentum. d. Stipules. e. Bracteoles. f. Flower without petals. g. Sepal. h. Petal. i. Fruit. j. Mericarp. k. Seed. (Based on: David s.n., MA-628480).

Fig. 735. Distribution of *Geranium moupinense*.

*umbelliforme*. It is easily differentiated from these species by its solitary cymules (not in umbel-like aggregates) with well-developed peduncles and pedicels. *Geranium moupinense* also has noticeably longer sepals, mucro, and nectaries, with a tuft of hairs at the top (not glabrous). Additionally, the leaves of *G. moupinense* have fewer lobes per segment. The bracteoles, sepals, and anthers are longer, and the eglandular hairs on the inflorescence are shorter. These features overlap to some degree. *Geranium moupinense* shares with *G. umbelliforme* a fruit rostrum with a well-developed narrowed apex. Unfortunately, among the few available collections, the fruits and underground parts are poorly represented. Thus, more collections may help to clarify the degree of character variation in both rootstock and fruits within this species.

*Geranium moupinense* is a rare species only known from three herbarium sheets, two at P and one at MA, which seems to be part of the same gathering. They bear a similar printed label with the date "1870". According to Franchet (1885), the collection by A. David was made in June 1869. Other species from the "Plantae Davidianae" have the same inconsistency (e.g., *Meliosma cuneifolia* Franch. [P-00732482], with a printed label dated 1870). Fortunately, in some cases the original handwritten label was kept (e.g., *Deutzia longifolia* Franch. [P-00709448], which shows that 1869 was changed to 1870 on the printed label). Yeo (1992) studied the specimens at P but considered the type as "not found". The present data strongly suggest that these specimens with only a printed label are original material, and consequently a lectotype was proposed. Yeo (1992) accepted *Geranium ascendens* in his treatment of Chinese geraniums, although he examined neither the type nor the other specimens. On the basis of the protologue he considered *G. ascendens* to be related to *G. moupinense* and *G. wardii* but only pointed out its

differences in regard to the latter. Xu & al. (1998) and Xu & Aedo (2008) considered *G. ascendens* a synonym of *G. moupinense*. An image of the type of *G. ascendens* fits well with *G. moupinense* because of its alternate cauline leaves, leaf lamina not deeply divided, and solitary cymules. These reasons support retaining *G. ascendens* in the synonymy of *G. moupinense*, at least until new evidence appears.

**Discussion.** *Geranium nakaoanum* is a small herb, with a vertical rootstock shortly branched at the apex and with short, erect, or ascending stems not rooting at the nodes. Basal leaves are arranged in a rosette, which is overtopped by the cymules. Cauline leaves are usually opposite, but in some individuals they are alternate in the middle of the shoot and opposite toward the apex. The cymules are borne on the short stem or, sometimes, on the rootstock. They are usually 1-flowered, although exceptionally some 2-flowered cymules occur in some predominantly 1-flowered individuals. The indumentum of the peduncles and pedicels consists of short, retrorsely appressed eglandular hairs. Both stems and petioles are glabrous, but some scattered, appressed, eglandular hairs were observed on the petioles of some individuals. Petals are long, with small hairs on the basal margin and on the base of the adaxial surface. The staminal filaments have a distinctive narrowed apex and conspicuous ciliae. The variability of *G. nakaoanum* fruits should be checked with more fruiting material because only two mature fruits have been studied. *Geranium nakaoanum* seems to be close to *G. polyanthes*, *G. umbelliforme*, and

*G. moupinense* because of its monochasial inflorescence. It differs, however, from this group by its usually opposite leaves. *Geranium nakaoanum* shows singular characters in the section, e.g., its usually 1-flowered cymules, the scarce indumentum, and the staminal filaments with a narrowed apex. According to Ikeda (*pers. comm.*), the description of *Geranium nakaoanum* was published in October 1954 (Hara 1954) and later copied in Flora and Fauna of Nepal (Hara 1955).

**292. *Geranium polyanthes*** Edgew. & Hook. f. in Hook. f., Fl. Brit. India 1: 431. 1874. TYPE LOCALITY: "Temperate Himalaya, Kumaon, Blinkworth; Inner valleys of Sikkim, alt. 9-12,000 ft., in grassy places, J. D. Hooker". TYPE: India. Uttaranchal, Kumaon, 29°24'N, 79°30'E, *R. Blinkworth* 8564 (lectotype, designated by Yeo 1992: 192, K-000380195!; isolectotypes, G-00402162 image!, P!, W!).

*Perennial herbs*, 7-64 cm tall. *Rootstock* 4-10 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, with thickened roots along the rootstock. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, subglabrous or with a variable indumentum composed by uncinete, eglandular hairs 0.1-0.3 mm long and, sometimes, patent, eglandular hairs 0.8-2.2 mm long and patent, glandular hairs 0.2-1.3 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves alternate in middle of shoot and upper opposite; leaf laminae (1.9)2.8-4.9(5.6) cm long, 2.7-6.5 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.61)0.71-0.76(0.81)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 3.4-8.9 mm wide at the base [ratio segment width at the base/middle segment length

= (0.20)0.25-0.30(0.33)], 3-10-lobed in distal half [ratio secondary sinus length/middle segment length = (0.12)0.17-0.22(0.32)]; petioles up to 32 cm long, without abscission zone, terete, not swollen, not deflexed in age, subglabrous or with a variable indumentum composed by uncinete eglandular hairs 0.1-0.3 mm long and, sometimes, patent, eglandular hairs 0.4-1.9 mm long and patent, glandular hairs 0.5-1.2 mm long; stipules 4.9-8.3 mm long, 1.5-4.8 mm wide, ovate, obtuse, free, papery, brown, with scattered, eglandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules 2(3)-flowered, in dense umbels-like aggregates at the top of each branch [ratio cymule length/leaf length = 1.4-3.4]; peduncles 5-73 mm long, with patent, eglandular hairs 0.6-0.7 mm long; bracteoles 2.3-5.6 mm long, 0.5-1.6 mm wide, lanceolate, obtuse, whorled; pedicels absent or (1.9)3.2-17(25) mm long, with uncinete, retrorse, eglandular hairs 0.2-0.3 mm long, patent, eglandular hairs 1-2.3 mm long and, usually, patent, glandular hairs 0.4-0.7 mm long. Flowers actinomorphic. *Sepals* (4.9)5.7-6.9(8.2) mm long, 1.7-3.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.4-0.9 mm long [ratio mucro length/sepal length = 0.06-0.16], with  $\pm$  patent, eglandular hairs 0.2-2.6 mm long and patent, glandular hairs 0.4-1.1 mm long on the abaxial surface, glabrous adaxially. *Petals* (7.8)9.3-11.8(14.1) mm long, 5.1-9.1 mm wide, erect-patent, rounded or retuse, without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.4-0.7 mm long. *Stamens* 10, both whorls bearing anthers; filaments 2.6-4.6 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.7 mm long; anthers 0.6-1.1 mm long, yellow. *Nectaries* 5, hemispheric, glabrous. *Gynoecium* 3.2-4.9 mm long, pink. *Fruit* 13-21.7 mm long, erect, discharge of carpel-projection type, operative;

mericarps 3.1-4.7 mm long, 1.2-1.7 mm wide, without a strand of fibers, not compressed at the apex, reticulate, without basal beak, without a basal callus, without a basal prong, brown, with  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long; rostrum 9.2-16.3 mm long, without a narrowed

apex or with a narrowed apex 0.5-1 mm long, not twisted, with patent, eglandular hairs 0.2-0.5 mm long and, sometimes, scattered, patent, glandular hairs 0.2-0.3 mm long; stigmatic remnants 0.7-1.7 mm long, with 5 glabrous lobes. *Seeds* 1.9-2.8 mm long, 0.9-1.4 mm wide, smooth, uniformly

colored, brown, glabrous. Cotyledons with entire margin. Fig. 738.

*Pollen*. *Erodium*-type (Aedo 2016: 615; Bortenschlager 1967: 456).

*Chromosome number*.  $2n = 28$ .

*Phenology*. Collected in flower from January to September.

*Distribution*. This species ranges from Uttaranchal in northern India to Yunnan in southwestern China (Fig. 739).

*Habitat*. Alpine meadows, moist fields, grassy slopes, damp banks, amongst boulders, and on edge of *Abies* Mill., *Juniperus* L., *Picea* A. Dietr., and *Rhododendron* L. forests; 2000-4600 m.

*Representative specimens examined*.

**Discussion.** *Geranium polyanthes* is an erect perennial herb with a more or less vertical rootstock with thickened roots, leaves alternate in the middle of the shoot and opposite at the apex, and with a monochasial inflorescence. It is easy to identify by its distinctive dense aggregate of cymules at the apex of each branch. The cymules usually lack pedicels, have short peduncles, and are subtended by sessile or short petiolate leaves. Exceptionally, some solitary, peduncled cymules occur in individuals with cymules predominantly in umbel-like aggregates. Stipules are ovate, obtuse, and conspicuously wide. *Geranium polyanthes* is close to *G. umbelliforme*, since both share a similar inflorescence structure and alternate cauline leaves. Nonetheless, *G. umbelliforme* has cymules in loose umbel-like aggregates usually with well-developed peduncles and pedicels and narrower stipules. According to Yeo (2002a), some of the flowers of *G. polyanthes* are cleistogamous.

**Discussion.** *Geranium strictipes* is an erect herb with a very stout, more

or less vertical rootstock, opposite leaves, and inflorescence a dichasial cyme with monochasial branches. According to Yeo (1992), *G. strictipes* is apparently the closest relative of *G. hispidissimum*. Their leaves, however, differ significantly. Leaves of *G. strictipes* are more deeply divided because the main and second sinuses are deeper. In addition, the main segment is narrower at the base in *G. strictipes*. The middle segment of the leaf lamina is rhombic in *G. strictipes*; in *G. hispidissimum* the middle segment is obtriangular. *Geranium strictipes* has longer petals, with more dense indumentum on the abaxial base, than in *G. hispidissimum*. The indumentum of *G. strictipes* varies, with some individuals subglabrous on stem and petioles, to others covered by a quite dense indumentum. The glandular hairs are sometimes absent on the stem and the petioles and vary greatly in density on the inflorescence. According to Yeo (1992), the glandular hairs of *G. strictipes* have distinctly small swollen heads, while in *G. hispidissimum* they have minute terminal cells, occasionally swollen but usually not. This feature seems to be constant in *G. strictipes* but varies in *G. hispidissimum*. In the latter, both glandular hairs with a minute or distinct head appear, which limits its taxonomic use. Franchet (1887: 442) described *Geranium strigosum* as a species without infraspecific taxa from "Yun-nan, in dumetis Pe-ngay-tze, supra Houangkia-pin; fl. fr. 4 sept. (Delav. n. )". Two years later Franchet (1889) recognized under his *G. strigosum* four varieties:  $\alpha$  *hispidissimum*,  $\beta$  *grandiflorum*,  $\gamma$  *gracile*, and  $\delta$  *platylobum*. Two of these are currently separated as *G. hispidissimum* (varieties  $\alpha$  and  $\delta$ ) (Yeo, 1992). Neither of the remaining two have the epithet "*strigosum*", which corresponds to the typical variety. However,  $\gamma$  *gracile* is described from two collections, the first being the same as *G. strigosum*: "In dumetis Pe-ngay-tze, supra Houang-kia-pin; fl. fr. 4 sept. 1882 (Delavay, *Geranium*, n. 2; in monte

Che-tcho-tze (id)". This strongly suggests that Franchet considered such variety as the typical, as Knuth (1912) indicated. Therefore, I lectotypified *G. strigosum* on *Delavay Geranium n. 2*. The result is that *G. strigosum* var. *gracile*, typified by Yeo (1992) on the same specimen, becomes homotypic of *G. strigosum*. Yeo (1992) was aware of this coincidence of localities but considered the type of *G. strigosum* as *non vidi*. Wu (1984) proposed the combination *Geranium strictipes* var. *grandiflorum*, which is not validly published according to article 41.5 of the ICN, because he cited the basionym and its author but without reference to its place of valid publication.

**294. *Geranium umbelliforme* Franch.,** Bull. Soc. Bot. France 33: 443. 1887. TYPE LOCALITY: "Yun-nan, in silvis ad juga Koua-la-po, supra Hokin, alt. 3000 m.; fl. 4 aug. 1885 (Delav. n. 1944)". TYPE: China. Yunnan, in silvis ad juga Koua-la-po, supra Hokin, 26°31'N, 100°11'E, 4 Aug. 1885, P.J. Delavay 1944 (lectotype, designated by Yeo 1992: 194, P-00757972!).

*Perennial herbs*, 28-45 cm tall. *Root-stock* 6-11 mm in diameter,  $\pm$  vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with patent, eglandular hairs 0.3-3.9 mm long and patent, glandular hairs 0.7-1.8 mm long. *Basal leaves* in a  $\pm$  persistent rosette, cauline leaves alternate in middle of shoot and upper opposite; leaf laminas (3.7)4.1-6.9(8.4) cm long, 4.9-9.9 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.66)0.67-0.73], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 8-14 mm wide at the base [ratio segment width at the base/middle segment length = (0.24)0.27-0.42(0.43)],

7-15-lobed in distal half [ratio secondary sinus length/middle segment length = (0.15)0.16-0.18(0.19)]; petioles up to 20 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.4-3.9 mm long and patent, glandular hairs 0.6-1.8 mm long; stipules 4.5-8.7 mm long, 1.2-

2.6 mm wide, ovate, obtuse, free, papery, brown, with scattered, eglandular and glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a monochasial cyme; cymules (2)3-4-flowered, in loose umbels-like aggregates at the top of each branch [ratio cymule length/leaf length = 1.3-2.4]; pedun-

Fig. 743. Distribution of *Geranium umbelliforme*.

cles 25-67 mm long, with patent, eglandular hairs 0.5-3 mm long and patent, glandular hairs 0.6-1.8 mm long; bracteoles 3.4-6 mm long, 0.3-0.7 mm wide, linear-lanceolate, whorled; pedicels (5)12-34(35) mm long, with patent, eglandular hairs 0.4-3.5 mm long and patent, glandular hairs 0.6-1.8 mm long. Flowers actinomorphic. *Sepals* 6.1-6.7(7.6) mm long, 1.7-2.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 0.5-1.4 mm long [ratio mucro length/sepal length = 0.09-0.18], with patent, eglandular hairs 0.3-3.3 mm long and patent, glandular hairs 0.6-1.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (13.1)13.8-15.2(16.8) mm long, 5-9 mm wide, erect-patent, rounded or retuse, without claw, purple, hairy on the base of both surfaces, mainly on adaxial surfaces, ciliate on the basal margin, with hairs 0.4-1 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.9-6.7 mm long, lanceolate, white, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.9 mm long; anthers 0.9-1.6 mm long, unknown color. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.3-6.2 mm long, red. *Fruit* 18.2-21.5 mm long, erect, discharge of carpel-projection type, operative; mericarps 2.8-3.4 mm long, 0.8-1.4 mm wide, without a strand of fibers, not compressed at the apex, reticulate, without basal beak, without a basal callus, without a basal prong,

brown, with  $\pm$  appressed, eglandular hairs 0.1-0.2 mm long; rostrum 12.3-15.9 mm long, with a narrowed apex 2-2.1 mm long, not twisted, with patent, eglandular hairs 0.3-0.4 mm long and, sometimes, scattered, patent, glandular hairs 0.2-0.3 mm long; stigmatic remnants 1.1-1.5 mm long, with 5 glabrous lobes. *Seeds* unknown. Cotyledons not studied. Fig. 742.

*Pollen*. *Erodium*-type (Aedo 2016: 615; Bortenschlager 1967: 456; Tan & al. 1996: 211).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower from July to August.

*Distribution*. This species ranges through Sichuan and Yunnan, in southwestern China (Fig. 743).

*Habitat*. Meadows and forest edges amongst the limestone cliffs; 3000-3400 m.

*Additional specimens examined*. **China.**

SICHUAN: Muli, 27°50'N, 101°15'E, 22 July 1921, *Kingdon Ward 4543* (E); Muli, mountains of Kulu, 27°50'N, 101°15'E, July 1929, *Rock 18042* (E, GH). YUNNAN: prefectura Dali, Henqing, pueblo Machang Baishanmu, 26°17'N, 100°16'E, 1 Aug. 1929, *Ching 23481* (PE); prefectura Dali, Henqing, pueblo Songgui, montaña Maer Shan Yanzidong, 26°22'N, 100°13'E, 21 July 1963, *Jinshajiang Exped. 4759* (KUN); au col de Koua-la-po, point culminant de la route de Ta-li à Hokin, 26°26'N, 100°6'E, 24 July 1883, *Delavay s.n.* (P); E flank of Lichiang Range, 27°25'N, 100°8'E, July 1910, *Forrest 6195* (BM, E, K, P).

*Discussion*. In its general aspect *Geranium umbelliforme* is similar to *G. polyanthes*. They share a similar inflorescence structure and alternate cauline leaves. Nonetheless, *G. umbelliforme* has cymules with usually well-developed peduncles and longer pedicels, resulting in a lax inflorescence. Petals of *G. umbelliforme* are longer and narrower than those of *G. polyanthes* and the narrowed apex of the fruit rostrum is longer. Additionally, the leaves of *G. umbelliforme* are longer and with more lobes per segment, bracteoles are narrower, sepal mucro is longer, and staminal filaments and anthers are longer. These

features overlap to some degree. Among the few available collections, the underground parts are poorly represented. Nevertheless, *Geranium umbelliforme* appears to have a more or less vertical rootstock. Only two specimens had fruits and the seeds are unknown because these fruits were immature. Thus, more collections may help to clarify the degree of character variation in both rootstock and fruits within this species. The ranges of these species do not overlap but are close; *Geranium polyanthes* occurs in the Himalayas in a zone about 2000 km from Uttaranchal in North India to Yunnan Province in China, whereas *G. umbelliforme* appears easternmost, in Yunnan and Sichuan Provinces.

**295. *Geranium wardii*** Yeo, Notes Roy. Bot. Gard. Edinburgh 34(2): 195. 1975. TYPE LOCALITY: "West Central Burma. Mount Victoria: common on turf slopes, mostly in young fruit, 2560 m, 26 x 1956, Kingdon-Ward 22760 (holo. BM!; iso. CGG!)". TYPE: Burma. Chin, West Central Burma, Mt. Victoria, 21°14'N, 93°55'E, 26 Oct. 1956, *F. Kingdon-Ward 22760* (holotype, BM-000796458!; isotypes, CGG, GB-0047721 image!).

*Perennial herbs*, 23-30 cm tall. *Rootstock* and roots unknown. *Stem* erect or ascending, leafy, not rooting at nodes, stolons absent, without vegetative stems, with scattered, patent, eglandular hairs 0.2-0.9 mm long. *Basal leaves* in a deciduous rosette, cauline leaves opposite; leaf laminae 2.2-3.3 cm long, 2.7-4.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = 0.57-0.60], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  appressed, eglandular hairs and plane glandular hairs on both surfaces; segments 5, in 1 plane, middle segment obtriangular, 5.4-7.7 mm wide at the base [ratio segment width at the base/middle segment

length = 0.33-0.38], 7-8-lobed in distal half [ratio secondary sinus length/middle segment length = 0.17-0.18]; petioles up to 6 cm long, without abscission zone, terete, not swollen, not deflexed in age, with patent, eglandular hairs 0.3-0.4 mm long and patent glandular hairs 0.7-1 mm long; stipules 2.8-5.5 mm long, 1.7-2.4 mm wide, ovate, obtuse, free, papery, brown, with eglandular and glandular hairs on the margin. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = 2-3.5]; peduncles 29-64 mm long, with uncinete, retrorse, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 0.4-0.8 mm long; bracteoles 4-4.5 mm long, 0.9-1.2 mm wide, broadly lanceolate, obtuse, whorled; pedicels 18-38 mm long, with uncinete, retrorse, eglandular hairs 0.2-0.3 mm long and patent glandular hairs 0.7-0.8 mm long. Flowers actinomorphic. *Sepals* 6.6-11 mm long, 3.4-4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro 1.1-1.2 mm long [ratio mucro length/sepal length = 0.10-0.18], with  $\pm$  patent, eglandular hairs 0.2-0.3 mm long and patent, glandular hairs 1-1.3 mm long on the abaxial surface, glabrous adaxially. *Petals* 12.6-13.4 mm long, 7.8-8.3 mm wide, erect-patent, rounded, without claw, purple, hairy on the base of the adaxial surface, glabrous abaxially, ciliate on the basal margin, with hairs 0.3-0.5 mm long. *Stamens* 10, both whorls bearing anthers; filaments 3.3-4 mm long, lanceolate, purple, pilose on the abaxial surface, ciliate on the proximal half, with hairs 0.3-0.5 mm long; anthers 1.4-1.5 mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.4-5 mm long, unknown color. *Fruit* 23-26 mm long, erect, discharge of carpel-projection type, operative; mericarps 3.4-5.2 mm long, 1.2-1.9 mm wide, without a strand of fibers, not compressed at the apex, reticulate, without basal beak, without a basal prong, brown, with  $\pm$  appressed, eglandular

hairs 0.2-0.3 mm long; rostrum 16-16.5 mm long, without a narrowed apex, not twisted, with patent, eglandular hairs 0.2-0.3 mm long; stigmatic remnants 1.9-2.5 mm long, with 5 glabrous lobes. *Seeds* 2.7-2.8 mm long, 1.5-1.6 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 744.

*Pollen*. *Erodium*-type (Aedo 2016: 615).

*Chromosome number*. Unknown.

*Phenology*. Collected in flower in October.

*Distribution*. This species is endemic to central Burma (Fig. 745).

*Habitat*. Turf slopes; 2550-2800 m.

*Discussion*. *Geranium wardii* is only known from the type, a flowering and fruiting collection. However, the specimens lack the rootstock and roots.

Fig. 744. *Geranium wardii*. a. Habit. b. Leaf. c. Bracteoles. d. Flower. e. Flower without petals and sepals. f. Sepal. g. Petal. h. Staminal filament. i. Fruit. j. Mericarp. k. Seed. (Based on: *Kingdon-Ward* 22760, BM).

Fig. 745. Distribution of *Geranium wardii*.

*Geranium wardii* shares with *G. strictipes* and *G. hispidissimum* opposite leaves and inflorescence in dichasial cyme, with monochasial branches. The leaves of *G. hispidissimum* are similar to those of *G. wardii* in the degree of division but have more lobes per segment and a denser indumentum. The petals of *G. wardii* and *G. strictipes* are longer than those of *G. hispidissimum*. In contrast, the sepal mucro of *G. wardii* is shorter than that of *G. strictipes* or *G. hispidissimum*, and the nectaries are glabrous (with a tuft of hairs in *G. strictipes* and *G. hispidissimum*). The stipules of *G. wardii* are ovate with an obtuse apex and resemble those of *G. nakaoanum*, *G. polyanthes*, and *G. umbelliforme*; in *G. strictipes* and *G. hispidissimum* the stipules are lanceolate.

**IVe. *Geranium* sect. *Ruberta*** Dumort., Fl. Belg.: 112. 1827. *Robertium* Picard, Mém. Soc. Agric. Boulogne-sur-Mer 1: 134. 1837. *Geranium* sect. *Robertium* (Picard) Godr. in Gren. & Godr., Fl. France 1: 306. 1847, nom. illeg. *Geranium* [§] *Robertiana* Boiss., Fl. Orient. 1: 871. 1867, nom. illeg. *Geranium* sect. *Robertiana* Boiss. ex Reiche in Engl. & Prantl, Nat. Pflanzenfam. 3(4): 9. 1908, nom. illeg. *Robertiella* Hanks in Hanks & Small, N. Amer. Fl. 25: 3. 1907, nom. illeg. TYPE: *Geranium robertianum* L. (art. 10.8).

*Geranium* sect. *Lucida* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 44, 60. 1912. TYPE: *Geranium lucidum* L. (art. 10.8).

*Geranium* sect. *Anemonifolia* R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 98. 1912. TYPE: *Geranium anemonifolium* L'Hér. (art. 10.8).

*Annual or perennial herbs. Flowers* predominantly actinomorphic. *Petals* rounded, with claw bicarinate. *Pollen* of *Geranium*-type. *Fruit* of carpel-projection type, operative; mericarps reticulate; rostrum not twisted. *Cotyledons* with entire margins.

*Geranium lucidum*, the type of section *Lucida*, has a distinctive calyx, with sepals having lengthwise keels and transverse flaps between these, and mericarps with cristate ribs clothed with hooked, small hairs. Those characters become blurred in *G. lasiopus* and *G. glaberrimum*; the sepals have nerves thickened into longitudinal ribs and, sometimes, with weak and incomplete transverse connections, and the mericarps are reticulate, sometimes with eglandular, not hooked hairs. Yeo (2004) recognized section *Lucida* as comprising the last three species despite the fact that he stated that there are links among all species (of sect. *Lucida* and sect. *Ruberta*). Consequently, the question arises as to whether it is necessary to have two sections, without clear boundaries, to accommodate 10 species. I preferred to recognize a broader and better characterized section *Ruberta*, which includes section *Lucida*, instead of separating these species into two sections following the previously mentioned proposal by Yeo (2004).

**Discussion.** *Geranium glaberrimum* is a perennial herb with a robust, more or less horizontal rootstock that shows some stipules and the petiole base. This species is almost completely glabrous. Some hairs, however, usually appear on the petal claw and on the mericarp surface and rarely on the staminal filament. The inflorescence is a dichasial cyme with monochasial branches. In each node, there is a pair of opposite leaves and a 2-flowered cymule. At the apex of each branch appears a solitary 2-flowered cymule or groups of several cymules. These groups are distinct, that is, with well-developed peduncles and pedicels. The flowers are actinomorphic. The outer sepals have the nerves thickened into longitudinal ribs and, sometimes, with weak and incomplete transverse connections. Yeo (2004: 412, 423) suggested that these features would indicate a link with *G. lucidum*. The stamens are a bit shorter than the petals, but they seem exerted because the petal blade is spreading. The staminal filaments and style are straight, not curved as in *G. macrorrhizum*, linear-lanceolate, without an expanded base, and usually glabrous. In some individuals, scattered cilia appear on the base (Sorger 73-13-32, W) or toward the apical half (Sorger 65-43-32, W; Sorger 67-5-62, W). When the fruit is still immature, the staminal

filaments remain appressed to the rostrum, protruding from the sepals, as in *G. macrorrhizum* and *G. dalmaticum*. The mericarps usually have a small number of short and usually hooked, eglandular hairs. These types of hairs are similar to those found in the mericarp of *G. lucidum*. One specimen has an unusual densely hairy mericarp (İlçim 450, MA), but otherwise it is very similar to *G. glaberrimum*. The mericarps usually have unelevated veins, slightly branched and with a veinless zone toward the ventral margin. One individual has raised ribs extending nearly to the ventral margin (Ulrich s.n., B) as was already noted by Yeo (2004: 423), but it matches *G. glaberrimum* otherwise. *Geranium glaberrimum* may be most closely allied with *G. lasiopis*; see under *G. lasiopis* for a discussion of the relation between the two species.

*Discussion*. *Geranium lasiopus* is similar to *G. glaberrimum*. As Yeo (2004) stated, both species are alike

Fig. 748. *Geranium lasiopus*. a. Habit. b. Leaf. c. Stipules. d. Bracteoles. e. Sepal. f. Petal. g. Petal claw. h. Flower without sepals and petals. i. Stamen. j. Fruit. k. Mericarps. (Based on: a, c-i, *Erik* 2272, W; b, j, k, *Sorger* 06-46-61, W).

Fig. 749. Distribution of *Geranium lasiopus*.

in habit, flower, and leaf shape. They also share outer sepals with the nerves thickened into longitudinal ribs, a bicarinate petal claw, and the presence of hooked, eglandular hairs on the mericarps. In contrast, *G. lasiopus* is easily distinguished from *G. glaberrimum* because its dense indumentum on the stem and leaves is mainly comprised of eglandular hairs. *Geranium lasiopus* has an unusual fruit with the narrowed apex much longer than the basal part of the rostrum. Unfortunately, *Geranium lasiopus* has been collected only a few times, and some aspects of its variability, such as the previously mentioned rostrum, remain unknown. The sepal longitudinal ribs and mericarp indumentum suggest that *G. lasiopus* is also close to *G. lucidum*. However, the latter has some important differences: annual life span, outer sepals with lengthwise keels, and transverse flaps between these, and smaller petals and mericarps with longitudinal cristate ribs. Davis (1967: 454) did not make a formal proposal of type for *Geranium lasiopus*. He only indicated a list of herbaria with original material of this species.

**Discussion.** *Geranium lucidum* is a small annual with a basal rosette and a more or less branched, erect stem. Cauline leaves are usually similar in shape to the basal leaves, becoming progressively shorter toward the shoot apex. The cauline leaves are alternate in the middle of the shoot (one to two nodes) and opposite toward the apex. The inflorescence is a dichasial cyme with monochasial branches. However, small or not well-developed individuals may show a monochasial inflorescence. This species is almost totally glabrous, although some hairs usually appear on the leaf, peduncles, and pedicels as well as the fruit. *Geranium lucidum* has a distinctive calyx because the three outer sepals have lengthwise keels and transverse flaps between these. The stamens are shorter than the petals, but they seem exserted because the petal blade is spread. The staminal filaments and style are straight, not curved as in *G. macrorrhizum*, linear-lanceolate, without an expanded base, and glabrous. The nectaries are strongly reduced, but nectar

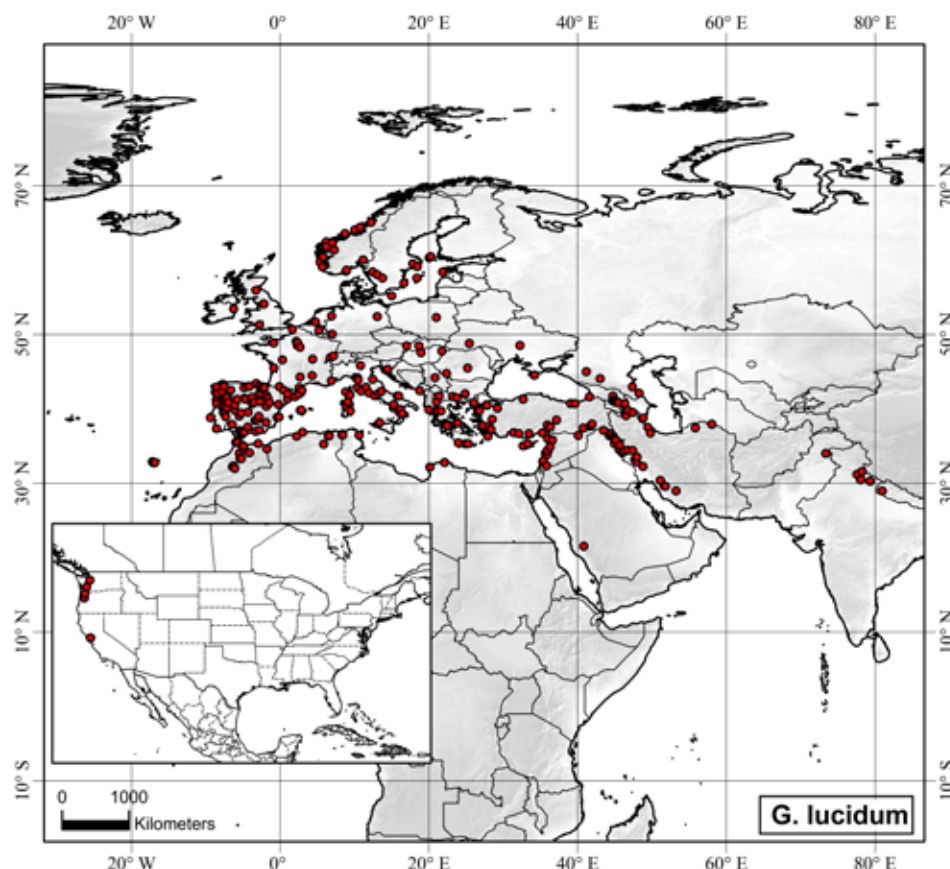

Fig. 752. Distribution of *Geranium lucidum*.

production has been documented by Yeo (2004: 421). The mericarps of *G. lucidum* are also unique in the genus because of their longitudinal cristate ribs with hooked small hairs. The fruit rostrum has a narrowed apex fully hairy. According to Yeo (2004), *G. lucidum* is close to *G. glaberrimum* because of its leaf shape and keeled calyx. Both species also share the presence of hooked glandular hairs on the mericarp, although they are not constant in *G. glaberrimum*.

*Geranium lucidum* is native to Europe, Central Asia (up to western Himalayas), and northern Africa. It is perhaps introduced in some areas of northern Europe. For instance, according to Weeda (1992) this species is introduced in the Netherlands. It is well documented as recently introduced in the western United States. Its presence in New Zealand, is based on a specimen at CHR could not be studied.

*Annual, sometimes biennial herbs*, 8-56 cm tall. *Stem* erect or prostrate, leafy, with  $\pm$  patent, glandular hairs 0.3-2.6 mm long, sometimes with uncinuate, eglandular hairs 0.2-1.3 mm long, rarely glabrous. *Basal leaves* in a persistent rosette, cauline leaves opposite (sometimes alternate in middle of shoot, 1-2 nodes); leaf laminas (0.9)2.3-5.7(7.1) cm long, 1.2-9.2 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, with  $\pm$  uncinuate, eglandular hairs (mainly on the nerves) and plane glandular hairs on both surfaces; segments (3)5, in 1 plane, middle segment rhombic, 0.3-1.1 mm wide at the base [ratio segment width at the base/middle segment length = 0.01-0.03(0.08)], 5-20(38)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.23)0.30-0.35(0.51)]; petioles up to 16 cm long, without abscission zone, terete, not swollen, somewhat deflexed in age, with patent, eglandular hairs 0.2-1 mm long and  $\pm$  patent, glandular hairs 0.4-2.9 mm long; stipules (0.7)1.2-2.4(5.3) mm long, 0.3-2.6 mm wide, ovate, obtuse, free, papery, green, with glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.7)1.1-2.2(6.4)]; peduncles (6.2)16.5-34.2(83) mm long, with uncinuate, retrorse, eglandular hairs 0.2-0.5 mm long and  $\pm$  patent, glandular hairs 0.2-2.2 mm long; bracteoles 0.4-1.6 mm long, 0.2-1.1 mm wide, ovate, whorled; pedicels (3.4)6.7-10.2(13.5) mm long, with uncinuate, retrorse, eglandular hairs 0.2-0.4 mm long and  $\pm$  patent, glandular hairs 0.2-1.5 mm long. Flowers actinomorphic. *Sepals* (3.7)4.9-6.3(7.9) mm long, 1.6-3.4 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.4)0.8-1.2(2) mm long [ratio mucro length/sepal length = (0.08)0.14-0.20(0.43)], with  $\pm$  patent, glandular hairs 0.2-2.4 mm long and, usually scattered, patent, eglandular hairs 0.2-0.5 mm long on the abaxial surface, glabrous adax-

ially. *Petals* (5.3)6.3-8.4(9.9) mm long, (0.8)1.5-2(2.6) mm wide, erect-patent, rounded (rarely retuse), with claw 3.2-6 mm long (bicarinated), purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments (3.7)5.2-6(6.6) mm long, linear-lanceolate, pink, glabrous; anthers (0.2)0.3-0.4(0.7) mm long, yellow. Nectaries 5, hemispheric, glabrous. *Gynoecium* 4.2-7.3 mm long, pink. *Fruit* (16.2)17.9-20.8(23.2) mm long, erect, discharge of carpel-projection type, operative; mericarps 1.9-3.2 mm long, 1-2.6 mm wide, usually with a strand of fibers derived from the beak attached near the apex on either side, not compressed at the apex, reticulate, with thick ridges dense throughout or sometimes thin and sparse in the basal half and forming 1-4 overlapping collars or contiguous circumferential ridges at apex, without basal beak, without a basal callus, without a basal prong, brown, glabrous or with eglandular hairs 0.1-0.2 mm long; rostrum 10-17.5 mm long, with a narrowed apex 4-8.3 mm long, not twisted, glabrous on the proximal half, and with patent, eglandular hairs 0.1-0.4 mm long and scattered, patent, glandular hairs 0.1-0.3 mm long restricted to the narrowed apex; stigmatic remnants 0.7-1.2 mm long, with 5 glabrous lobes. *Seeds* 1.5-2.3 mm long, 0.8-1.3 mm wide, smooth, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 753-755, 757 k-o.

*Pollen*. *Geranium*-type (Aedo 2017: 412; Stafford & Blackmore 1991: 76; Velasco 1992b: 60; Verhoeven & Marais 1990: 167).

*Chromosome number*.  $2n = 32$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges through Europe, western Asia (to northern Iran) and northern and eastern Africa and it is introduced in California, southern South America, Korea, Australia, New Zealand and South Africa (Fig. 756).

*Habitat*. Roadsides, clearings and disturbed areas, dunes, rocky and shrubby areas and forests; 0-3100 m.

*Representative specimens examined.*

**Discussion.** *Geranium purpureum* is an annual that facultatively behaves as a biennial if it is sown in summer (Yeo 1973a: 291). It usually has an erect habit, although some plants from exposed habitats may be prostrate. The leaves are palmatisect, with a distinctly petiolulate main segment. The cauline leaves are alternate occasionally at one or two middle nodes but become opposite toward the inflorescence. The flowers are small,

actinomorphic, with the petals a little longer than the sepals. The petal size and color of the anthers are always quite sufficient to distinguish *G. purpureum* from *G. robertianum*, at least in the living state. The petal length of *G. purpureum* [(5.3)6.3-8.4(9.9) mm] shows a small degree of overlap with that of *G. robertianum* [(8.5)10.5-12.5(14.2) mm]. The petal width, which is measured on the blade, also shows a minimum overlap [(0.8)1.5-2(2.6) mm in *G. purpureum*, (2.1)2.6-4.5(6.1) mm in *G. robertianum*]. The anthers of *G. purpureum* are yellow, while those of *G. robertianum* are purple. In some taxonomic accounts there has been confusion between anther color and pollen color of these species (i.e., Carolin 1965: 331; Webb & Ferguson 1968: 194), and "orange pollen" has been attributed to *G. robertianum*. Both species, however, have yellow pollen. The variability of mericarp indumentum and sculpture of *Geranium purpureum* is considerable and this has led to the description of a number of minor variants as species. Baker (1955, 1957) and Yeo (1973a) analyzed this variability, concluding that it has little taxonomic significance. The mericarps of *G. purpureum* vary from glabrous to densely hairy, with short eglandular hairs. As Yeo (1973a) pointed out, this variability can be occasionally found on the same individual. During this study it has been corroborated, for instance, in a specimen from Turkey (*Castroviejo 15211*, MA), which has glabrous mericarps (mature and immature), some with few hairs and others more or less densely hairy. The sculpture of the mericarp varies in the presence of one to four overlapping apical collars, the thickness of the ridges, and the density of the reticulum. Some mericarps have apical collars in a variable number and others none; some have thick and contiguous ridges, with no space between them; and others have thin ridges with wide gaps between them. In some cases, the ridges occur throughout the surface of the mericarps, while in others

they are sparse or lacking in the basal half. In some herbarium specimens, it has been observed that mature mericarps have thick and contiguous ridges, while immature mericarps show thin ridges with wide gaps between them (i.e., *Castroviejo 15211*, MA; *Rechinger 23009*, MA). These findings corroborate Yeo's (1973a) statement that the sparser and more slender ribbing may also be partially connected with immaturity. Yeo (2004) also mentioned that the weakness of the sculpture in mericarps may be related to maturation in adverse summer weather. In some areas, like Macaronesia, Caucasia, or East Tropical Africa, herbarium specimens with thick and contiguous ridges are rare or lacking. This should be further investigated. However, it seems difficult that the sculpture and mericarp indumentum can be consistently used to segregate any taxon from *G. purpureum*. It also should be noted that some herbarium specimens that lack flowers and have mericarp with thin and sparse ridges are impossible to assign with certainty to *G. purpureum* or to *G. robertianum*. Figures 753 and 754 show the variability of mericarp sculpture in *G. purpureum*.

Baker (1955) accepted *Geranium purpureum* subsp. *forsteri* as an endemic to South England, based mainly on its prostrate habit. Yeo (2003) grew plants from seeds and found that some individuals can have an erect habit. Yeo (2003) expressed doubt about a more acceptable rank for this entity, but concluded that it can be maintained as a subspecies. Finally, subsp. *forsteri* is mentioned but is not formally recognized by Yeo (2004). Considering the previously mentioned variation of the habit, and the fact that no relevant additional character has been found, the subspecies *forsteri* was synonymized to *G. purpureum*.

Davis (1967: 452, 458) recognized *Geranium eginense* as a distinct species endemic to Turkey and only known from the type gathering. According to this author, *G. eginense*

can be distinguished from *G. purpureum* and *G. robertianum* by its leaf segments 2- to 3-lobed and obtusely crenate-dentate. Schönbeck-Temesy (1970: 38) suggested, however, that *G. eginense* is quite similar to some specimens of *G. purpureum* and is very difficult to distinguish from it. An examination of the type of *G. eginense* shows a plant like *G. purpureum* in habit but reduced in size, with short petals and mericarps with prominent ridges. The only feature that could support the recognition of *G. eginense* is the lack of fibers derived from the rostrum and attached near the apex of the mericarp. Yeo (1973a: 343) mentioned a similar case of a plant with these characters cultivated at Cambridge from seeds received from *Jardim Botânico da Universidade do Porto*. I have found these characters widespread among herbarium specimens (i.e., from Cyprus, Iter Medit. IV 1592, MA-495364; Montenegro, *Krendl s.n.*, 25 June 1988, W; and Tunisia, *Walter 549*, W); even on the same individual (i.e., *Castroviejo 15211*, MA). All these plants showed no noticeable variation in other characters, which suggests that the occasional lack of fibers is of minor taxonomic significance.

*Geranium elamellatum* is described by Kokwaro (1969) as an endemic species from eastern Africa. The main distinction from *G. purpureum* proposed by Kokwaro (1969: 528) is the sculpture of the mericarp, with thin ridges, sparse and scarcely anastomosing in the basal half. As stated before, this pattern is found to be widespread through where *G. purpureum* is found, from Armenia (*Vitek 12-0326*, W) to the Azores (*Aedo 19458*, MA).

I visited the *Muséum d'histoire naturelle de Grenoble*, where Villars' herbarium is kept, to locate the original material of *Geranium purpureum*. I also searched for this material at G, MPU, and P, where some of Villars' duplicates can be found. Unfortunately, the search yielded no positive results. Some specimens, however, have been found in Willdenow's her-

barium (B). The folder B-W-12583, which includes three sheets, has a small label on the inner side written in Schlechtendal's hand indicating "Villars. W." According to R. Vogt and P. Hiepko (*in litt.*), this label means that these specimens were provided by Villars to Willdenow. The three sheets were annotated as "*G. robertianum* var. *purpureum*" by R. Knuth and are in accordance with the current concept of *G. purpureum*. The sheet selected as lectotype (B-W-12583-02-0) shows a fruiting plant plus a fragment, with some cymules in flower. Unfortunately, there is no indication of the exact geographic origin of this collection. In the protologue, Villars (1786: 272) mentioned only one locality, near Grenoble: "au Pont de Claix, sur les rochers", 45°07'N, 5°43'E, and later states: "Je l'ai trouvée au Buis [45°26'N, 05°02'E], sous les rochers, à Grenoble près le pont de Claix & ailleurs" (Villars 1789: 375). When Lojacono (1906) described *Geranium robertianum* var. *insigne*, he indicated the locality and the collector: "Villarsa Tin.!" According to G. Domina (*in litt.*), the specimen selected as type was collected by Tineo and relabeled by Lojacono (Lojacono 1906); thus, to avoid any uncertainty, it is chosen as neotype instead of lectotype.

A detailed account of the life history of *G. purpureum* is provided by Tofts (2004b).

VII. 1972. Leg. A. Petrova (SOM-130339)". TYPE: Bulgaria. Pirin septentrionalis, Markovo, pr. Bansko 41°50'N, 23°29'E, 2 July 1972, *A. Petrova s.n.* (holotype, SOM-130339!).

*Biennial, sometimes annual herbs*, 10-67 cm tall. *Stem* erect or prostrate, leafy, with ± patent, glandular hairs 0.7-2.8 mm long, sometimes with uncinete, eglandular hairs 0.2-0.7 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminas (3.5)4.4-7(10) cm long, 3.2-10.1 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± uncinete, eglandular hairs (mainly on the nerves) and plane glandular hairs on both surfaces; segments (3)5, in 1 plane, middle segment rhombic, 0.2-1.4 mm wide at the base [ratio segment width at the base/middle segment length = 0.01-0.02(0.04)], 16-37(49)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.18)0.29-0.35(0.42)]; petioles up to 19 cm long, without abscission zone, terete, not swollen, deflexed, appressed to the soil in age, with retrorse, not appressed, eglandular hairs 0.2-0.6 mm

long and patent, glandular hairs 0.3-3.1 mm long; stipules (1.6)2-4.1(4.9) mm long, 0.8-2.5 mm wide, ovate, obtuse, free, papery, green, with glandular hairs on abaxial surface and on the margin, glabrous adaxially. *Inflorescence* a dichasial cyme with γ monochasial branches; cymules 2-flowered, solitary [ratio cymule length/leaf length = (0.6)0.9-2.2(5.5)]; peduncles (13)27-54(94) mm long, with uncinete, retrorse, eglandular hairs 0.1-0.5 mm long and ± patent, glandular hairs 0.3-2.9 mm long; bracteoles 0.6-1.8 mm long, 0.2-1 mm wide, ovate, whorled; pedicels (3.4)5.9-12.1(19.6) mm long, with uncinete, retrorse, eglandular hairs 0.2-0.4 mm long and ± patent, glandular hairs 0.2-2.2 mm long. Flowers actinomorphic. *Sepals* (5)5.6-6.5(7.2) mm long, 1.6-3.9 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.9)1.2-1.8(2.6) mm long [ratio mucro length/sepal length = (0.14)0.22-0.31(0.44)], with ± patent, glandular hairs 0.4-3.5 mm long and, usually scattered, patent, eglandular hairs 0.1-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* (8.5)10.5-12.5(14.2) mm long, (2.1)2.6-4.5(6.1) mm wide, erect-patent, rounded, with claw 3.1-5.9 mm long (bicarinated), purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments (4.5)6.1-7.3(8) mm long, linear-lanceolate, pink, glabrous; anthers (0.4)0.5-0.6(0.7) mm long, purple. Nectaries 5, hemispheric, glabrous. *Gynoecium* 5.5-8.6 mm long, pink. *Fruit* (17.4)20.2-22.6(24.4) mm long, erect, discharge of carpel-projection type, operative; mericarps 2.1-3.2 mm long, 1-1.5 mm wide, with a strand of fibers derived from the beak attached near the apex on either side, not compressed at the apex, reticulate, with few thin ridges and scarcely anastomosing in the basal half but more abundant distally and forming 1-2(3) overlapping, collar-like keels at the apex, without basal beak, without a basal callus, without a basal prong, brown, glabrous or with eglandular hairs 0.1-0.2 mm long; rostrum 13.2-18.2 mm long, with a narrowed

apex 4.4-7.2 mm long, not twisted, glabrous on the proximal half, and with patent, eglandular hairs 0.1-0.3 mm long and scattered, patent, glandular hairs 0.1-0.3 mm long restricted to the narrowed apex; stigmatic remnants 0.9-1.9 mm long, with 5 glabrous lobes. *Seeds* 1.3-2.3 mm long,

0.8-1.4 mm wide, smooth, uniformly colored, brownish red, glabrous. Cotyledons with entire margin. Figs. 757 a-j, 758, 759.

*Pollen*. *Geranium*-type (Aedo 2017: 412; Bortenschlager 1967: 425; Park & Kim 1997: 312; Perveen & Gaiser 1999: 267; Stafford & Blackmore

1991: 74; Tan & al. 1996: 210; Velasco 1992b: 60; Weber 1996: 196).

*Chromosome number*.  $2n = 32?$ ,  $52?$ ,  $54?$ ,  $56?$ ,  $64$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species ranges through Europe, western and central Asia and northern Africa and perhaps on some parts of eastern U.S.A. and it is introduced in southwestern Canada, western U.S.A., Bermuda, southern South America, China, Taiwan, Réunion, Japan and New Zealand (Fig. 760).

*Habitat*. Disturbed areas, mossy rocks, dunes, pastures, and deciduous or mixed forests; 0-3500 m.

**Discussion.** *Geranium robertianum* is a facultative biennial, occasionally lasting longer in protected conditions or sometimes annual (Bertin, 2001; Tofts, 2004a; Yeo, 1973a). It is quite similar to *G. purpureum* in general appearance, leaf outline, inflorescence structure, and flower and fruit morphology; however, *G. robertianum* has longer and wider petals and purple anthers as stated before. Moreover, the sepal mucro and anthers are longer in *G. robertianum* than in *G. purpureum* although with some overlap. In contrast with *G. purpureum*, the mericarp sculpture of *G. robertianum* is less variable. These mericarps have scarce and thin ridges anastomosing in the basal half but are more abundant distally and form one to two (or three) overlapping, collar-like keels at the apex. This type of sculpture is also found in some specimens of *G. purpureum*, which make it difficult to assign some herbarium specimens without

flowers to either species. Figure 758 shows the variability of mericarp sculpture in *G. robertianum*. Baker (1956) accepted *Geranium robertianum* subsp. *maritimum* based on its prostrate habit and lack of indumentum, and *G. robertianum* subsp. *celticum* based on its pale leaves and flowers. Yeo (1973a, 2004) has reservations as to the distinctness and constancy of these taxa and does not formally recognize them. I agree with this opinion, and, considering that no relevant additional characters have been found, these subspecies were synonymized to *G. robertianum*. Yeo (1992, 2004) reported the smaller flower size of *G. robertianum* from China and the Far East (in relation to the European populations), which has been corroborated in this study. Otherwise, they fall well within the range of variability of *G. robertianum*. According to the cytological observations by Baker, Yeo (1973a: 314) reported that the triploid hybrid of *Geranium purpureum* × *G. robertianum* formed *n* univalents and *n* bivalents at the first division of meiosis. Consequently, Yeo (1973a: 314) proposed an allopolyploid origin for *G. robertianum* with *G. purpureum* and an unknown species as parents.

A detailed account of the life history of *G. robertianum* is provided by Tofts (2004a) and Bertin (2001). Sexton & al. (1983) studied the abscission process of the petals of *G. robertianum*.

*Geranium robertianum* is widely distributed in the temperate northern hemisphere and is naturalized in southern South America, Réunion, and New Zealand (Aedo 2012). Its status in North America is subject to controversy: it is naturalized in southwestern Canada and the western United States, but is perhaps native to eastern Canada and the eastern United States, where its presence was documented at an early date (Pursh 1814). *Geranium robertianum* appears to be introduced in eastern Asia and Japan, but Nishida & al. (2012) suggested that some Japanese populations could be native. *Geranium robertianum* was recorded from Singapore (Knuth 1912: 66) based on a collection by J. C. Ploem from 1867, probably kept at B. Unfortunately, no voucher of this record has been located. It was not possible to locate the type of *Geranium robertianum* var. *rubricaulle* Hornem. According to Wilmott (1921: 98), no original specimens are at C, where Hornemann's herbarium is kept.

**Discussion.** *Geranium yeoi* is a robust biennial herb with a simple taproot with thin secondary roots. It is an unique endemic species from Madeira without a well developed caudex. According to Yeo (1973a: 289), cultivated plants form magnificent overwintering rosettes. *Geranium yeoi* is extremely similar to *G. robertianum* but larger in all its parts. It is easy to distinguish, however, by its longer petals with a longer claw, longer staminal filaments, and longer fruits. According to Yeo & Widler-Kieffer (1990: 11) the "nectar of *G. yeoi* [as *G. rubescens*], contains exactly the same amino-acids as that of *G. robertianum*, as indeed we would expect if it was an autopolyploid of the latter". *Geranium yeoi* is also characterized

by the lack of fibers derived from the rostrum and attached near the apex of the mericarp. In some specimens (i.e., *Jardim* s.n., MADJ-8920), however, vestigial fibers have been found at the apex of the mericarp, which reinforces the close relationship between *G. yeoi* and *G. robertianum*. Although *Geranium yeoi* is more similar in life cycle to *G. robertianum* than *G. palmatum*, it may be difficult to differentiate from *G. palmatum* when the basal part of the plant is not collected. *Geranium yeoi* has, however, shorter and narrower petals, but with a larger claw, than *G. palmatum*. The staminal filaments, anthers, and fruit rostrum apex are also shorter in *G. yeoi* than in *G. palmatum* with little overlap. Additionally, *G. yeoi* may be distinguished by its lack of a purplish pigment in the stalk of the glandular hairs of the inflorescence.

*Geranium yeoi*, a restricted endemic from the northern slopes of Madeira Island, has been used often in gardens (Yeo 2002a: 178). It is naturalized or garden-escaped in Great Britain (Stace 2010), France and in several remote places, such as in California, Australia, and New Zealand.

**Discussion.** *Geranium cataractarum* is a perennial herb with a branching rootstock that bears several rosettes. The erect aerial stem ends in a dichasial inflorescence with distinct 2-flowered cymules. The leaves are opposite and palmatisect, and quite similar to those of *G. robertianum* in shape and the degree of division. The flow-

ers show the two upper petals with a divergent petal blade; otherwise they are actinomorphic. The petals are glabrous and have a bicarinate claw, but they are not arranged together with the stamens to form five nectar passages. The staminal filaments are narrow and shorter than the petals, but they seem exerted because the petal blade is spreading. When the fruits are still immature, the staminal filaments remain appressed to the rostrum, protruding from the sepals, but considerably less than in *G. macrorrhizum*. The indumentum consists predominantly of long glandular hairs in a variable density. Scattered, eglandular hairs are also found, especially on the peduncles and pedicels. Mericarps are usually glabrous, with a reticulate surface, with two to three more prominent longitudinal, parallel veins that are connected by small transversal ones. The rostrum may be glabrous or, more frequently, with scattered, short glandular hairs restricted to the basal half of the narrowed apex. *Geranium cataractarum* was classified into section *Unguiculata* by Knuth (1912: 89) with some doubts, which was later accepted by Yeo (1984). Van Loon (1984b: 287) remarked on the morphological affinities and chromosomic relation among *G. cataractarum*, *G. robertianum*, and *G. purpureum* and placed *G. cataractarum* into *Geranium* sect. *Robertia*, which is also recognized by Yeo (2004). The actinomorphic flower and bicarinate petal claw strongly support the latter classification.

**Discussion.** *Geranium maderense* is similar to *G. palmatum* and *G. reuteri*. They share a pachycaul habit, giant inflorescences, and dissected leaves. *Geranium maderense* is differentiated by its massive caulescent habit and its immense inflorescence. According to Yeo (1973a), the monocarpic *G. maderense* has one extended internode terminating the central axis and four to eight crowded inflorescence branches at the apex, as well as a terminal flower vestige, while *G. palmatum* and *G. reuteri* continue to produce leaves on the central axis above the origin of the inflorescence branches. As commented in *G. palmatum* and *G. reuteri*, the rootstock of *G. maderense* has marked petiole scars and reflexed petioles toward the apex that provide support to the plants. Similarly, it also has a predominantly glandular indumentum with a purple-tinted stalk. *Geranium maderense* is easily distinguished from *G. palmatum* and *G. reuteri* by its shorter staminal filaments, usually as long as the sepals, and by its shorter, narrowed apex of the rostrum. The peduncles, pedicels, meri-

carps, and seeds of *G. maderense* are longer than those in *G. palmatum* and *G. reuteri*, and the petal claw is shorter, in all cases with some overlap. *Geranium maderense* and *G. palmatum* share wider petals than *G. reuteri*, and a rostrate narrowed apex with glandular hairs on the basal half. The rostrum of the fruit of *G. maderense* and *G. palmatum* is shorter than that in *G. reuteri* and the stigmatic remnants are longer. *Geranium maderense* and *G. reuteri* share longer sepals with a shorter mucro than in *G. palmatum*, and in both cases with some overlap. Additionally, it should be mentioned that *G. palmatum* has tomentose stipules, while those of *G. maderense* and *G. reuteri* have scattered hairs. Wilder-Kiefer & Yeo (1987: 287) reported that the hybrid of *Geranium maderense* × *G. cataractarum* formed ca. 16 univalents and ca. 18 bivalents at the first division of meiosis, which strongly suggests an allopolyploid origin for *G. maderense*, with *G. cataractarum* and an unknown species as parents.

*Geranium maderense* is widely cultivated in Madeira, in gardens, and is naturalized near cities. It is, however, very rare in the wild. *Geranium maderense* was first discovered by Costa in 1934 (Pereira 1967). This author collected the plant "...nas rochas escarpadas do litoral das Achadas da Cruz..." in the northwestern part of the island. In Pereira (1967) it was recognized as "nova espécie" described in Portuguese and photographed, but, unfortunately, no epithet was provided. Yeo (1969) formally described *G. maderense* from plants collected by Major C.H.C. Pickering, a British resident in Madeira. This collector located a wild population on Levada do Moiro, a mountain place (1200 m) far from coastal cliffs. According to R. Jardim (*in litt.*), an expert local botanist, this population would be of anthropic origin. The species has also been observed and recently collected by R. Jardim and M. Sequeira on the craggy coastal cliffs east to Porto da Cruz, Larano; this seems the only native locality extant today. *Ge-*

*ranium maderense* is widely used in gardens. Its presence in New Zealand, probably as garden-escape, is based on a specimen at AK that could not be studied.

**Discussion.** *Geranium palmatum* is similar to *G. reuteri*. They share a pachycaul habit, giant inflorescences, and dissected leaves. The rootstock also has marked petiole scars and reflexed petioles toward the apex that provide support to the plants. *Geranium palmatum* growth continues after flowering by the production of rosette leaves above the inflorescence branches. The inflorescence is basically dichasial with 2-flowered cymules, but the suppression of internodes, the absence of growth in certain axes, and the abortion of flowering peduncles combine to display a complex inflorescence with numerous flowers together. The indumentum of *G. palmatum* also consists predominantly of long glandular hairs, with a purple-tinted stalk, variable in density, although some eglandular hairs are also found, especially on the peduncles, pedicels, and leaf nerves. The color of the hair stalks is sometimes difficult to appreciate in dry specimens. The most noticeable differences in relation to *Geranium reuteri*, as already mentioned, are the wider petals of *G. palmatum* and its glandular hairs on the fruit rostrum. Additionally, *G. palmatum* has tomentose stipules, while *G. reuteri* has stipules with scattered hairs. The fruit of *G. palmatum* is shorter but with longer stigmatic remnants, in both cases with some overlap. The lectotype of *Geranium palmatum* consists of a fragment of inflorescence and a leaf. The middle leaf segment is clearly petiolulate, the stipules are tomentose, and the petals are 11–12 mm wide, which fit very well in the current concept of this species. The fruit rostrum, however, has only eglandular hairs. Because it is an old specimen, glan-

dular hairs could have been lost or, alternatively, it may be an exception to the normal glandular rostrum indumentum of this species.

*Geranium palmatum*, a restricted endemic from Madeira Island, has been used often in gardens (Yeo 2002a). It is occasional in California (Aedo 2012: 5).

*Perennial herbs*, 23-51(150) cm tall. *Rootstock* 4.5-17.4 mm in diameter, ± vertical, not tuberculate, not turnip-shaped, without thickened roots. *Stem* simple or with several short branches, each axis terminating in a rosette, erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, usually glabrous, sometimes with with uncinate, eglandular hairs 0.3-0.4 mm long and scattered, patent, glandular hairs 0.9-1.4 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminas (7)8-21(27) cm long, 7-28 cm wide, not peltate, palmatisect, polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± appressed, eglandular hairs and plane glandular hairs on the adaxial surface and glabrous or with scattered, eglandular and glandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 1.7-4.2 mm wide at the base [ratio segment width at the base/middle segment length = (0.01)0.02-0.04], 33-104(270)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.35)0.36-0.51(0.57)]; petioles up to 32 cm long, without abscission zone, terete, with swollen base, deflexed and remaining turgid after lamina death, usually with patent, glandular 0.3-1.6 mm long, sometimes with uncinate, retrorse, eglandular hairs 0.2-0.5 mm long, rarely glabrous; stipules

(1.5)3-6.8(11) mm long, 1.9-7.7 mm wide, broadly lanceolate to ovate, obtuse, free, papery, green, with eglandular and glandular hairs on abaxial surface and margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules (1)2(4)-flowered, solitary [ratio cymule length/leaf length = 1.1-2.8]; peduncles (18)36-47(87) mm long, with uncinate, retrorse, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.4-1.6 mm long; bracteoles 0.5-2.4 mm long, 0.4-1.7 mm wide, ovate, whorled; pedicels (2)11-25(39) mm long, with uncinate, retrorse, eglandular hairs 0.2-0.5 mm long and patent, glandular hairs 0.4-1.7 mm long. Flowers actinomorphic. *Sepals* (7.3)7.4-8.3(9.3) mm long, 2.2-3.7 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.7)1.2-1.7(3) mm long [ratio mucro length/sepal length = (0.09)0.16-0.21(0.41)], with ± patent, glandular hairs 0.4-1.6 mm long and, usually, patent, eglandular hairs 0.2-0.5 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.1)14.4-19.4(21) mm long, (2.8)5.4-5.9(6.4) mm wide, ± patent, rounded (rarely retuse), with claw 4.2-7.1 mm long (bicarinated), purple, glabrous. *Stamens* 10, both whorls bearing anthers; filaments (14.8)16-19(19.6) mm long, linear-lanceolate, white or deep red, glabrous; anthers (1.1)1.6-1.7(2.4) mm long, maroon to scarlet. Nectaries 5, hemispheric, glabrous. *Gynoecium* 12-23 mm long, pink. *Fruit* (27)33-38(41) mm long, erect, discharge of carpel-projection type, operative; mericarps 3.9-4 mm long, 1.2-1.6 mm wide, without a strand of fibers, not compressed at the apex, reticulate, with thin ridges scarcely anastomosing and forming 0-1 overlapping, collar-like keels at the apex, without basal beak, without a basal callus, without a basal prong, brown, glabrous or with eglandular hairs 0.1-0.2 mm long at apex; rostrum 26-34 mm long, with a narrowed apex 14-21 mm long, not twisted, with scattered, patent, eglandular hairs 0.1-0.3 mm long restricted to the basal half of the narrowed apex; stig-

matic remnants 1.3–3 mm long, with 5 glabrous lobes. *Seeds* 2.3–3 mm long, 0.9–1.4 mm wide, smooth, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 773, 774.

*Pollen*. *Geranium*-type (Aedo 2017: 412).

*Chromosome number*.  $2n = 128$ .

*Phenology*. Collected in flower from January to December.

*Distribution*. This species is endemic to Canary Island (Fig. 775).

*Habitat*. In the shade of cloud forests and *Erica* L. formations; 200–1600 m.

*Representative specimens examined.*

**Discussion.** *Geranium reuteri* is a perennial with a rootstock terminating in a rosette. The rootstock, which is tapered toward the base, has marked petiole scars and petiole remaining toward the apex (this apical part is unburied). The reflexed petioles provide support to the plants as in other related species. According to Yeo (1973a: 291), *G. reuteri* continued its growth after flowering by the production of rosette leaves above the inflorescence branches. *Geranium reuteri* produces a terminal inflorescence with axillary branches arising from the uppermost rosette leaves. The production of a terminal whorl of inflorescence branches is followed by the death of the subtending rosette. The plant normally survives by producing a few axillary rosettes from the lowest internodes of the stem. Yeo (1973a: 292) indicated that the inflorescence is basically dichasial with 2-flowered cymules, but the suppression of internodes, the absence of growth in certain axes, and the abortion of flowering peduncles combine to display a complex inflorescence with numerous flowers together. *Geranium reuteri* has a perfectly actino-

morphic flower with narrow, spreading petal limbs, long stamens, and a style exerted far beyond the petals. The indumentum of *G. reuteri* consists predominantly of long glandular hairs, with a purple-tinted stalk, variable in density. Scattered eglandular hairs are also found, particularly on the peduncles, pedicels, and leaf nerves. According to Yeo (1973a: 294), *Geranium reuteri* shows a continuous ring of sclerenchyma in the petiole, while in other species of the group (species 299-301, 303-304) this ring is interrupted. Yeo (1973a: 322) distinguished *G. reuteri* because its leaves have a sessile middle leaf segment, in contrast to the petiolulate middle leaf segment of *G. palmatum* and *G. maderense*. In *G. reuteri* the middle segment narrows progressively toward the base, and in some cases it is difficult to ascertain whether there is a short petiolule. *Geranium palmatum* and *G. maderense*, however, have a middle segment that narrows abruptly into a distinct petiolule. *Geranium reuteri* is similar to *G. palmatum* in having very long stamens exerted far beyond the throat. However, in *G. reuteri* the corollas are perfectly actinomorphic, whereas in *G. palmatum* they are slightly zygomorphic. Although they have some overlap, the sepals are longer in *G. reuteri* than in *G. palmatum* but with a shorter mucro. Petals are also shorter but with a longer claw. The best features to differentiate between the two species, however, are petal width and rostrum indumentum. Petals are clearly wider in *G. palmatum* than in *G. reuteri*. The narrowed apex of the rostrum of *G. reuteri* has short eglandular hairs mainly on the basal half, whereas *G. palmatum* has glandular and eglandular ones. When Reuter (1858) described *Geranium canariense*, he indicated only the locality and the collector: "Hab. in Teneriffa, Webb, Bourgeau pl. exsicc.! G. anemonefolium Webb Phyt. can. I p. 20; Bourg. pl. exsicc. n° 1251 non L'Hér." According to Yeo (1973a: 332), Reuter's citation of the number 1251 was an error for 1271.

*Perennial herbs*, 21-52 cm tall. *Rootstock* 4.7-10.6 mm in diameter, ± horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy, not rooting at nodes, stolons absent, without vegetative stems, with uncinat, eglandular hairs 0.1-0.3 mm long and, usually, scattered, patent, glandular hairs 0.2-1 mm long. *Basal leaves* in a persistent rosette, cauline leaves opposite; leaf laminae (4.4)5.2-8.7(10.8) cm long, 4.7-10.7 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.70)0.74-0.81(0.85)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with ± appressed, eglandular hairs and plane glandular hairs on the adaxial surface and with uncinat, eglandular hairs and glandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 5.3-15.4 mm wide at the base [ratio segment width at the base/middle segment length = (0.16)0.17-0.26(0.33)], (8)10-34-lobed in distal half [ratio secondary sinus length/middle segment length = (0.11)0.16-0.21(0.27)]; petioles up to 23 cm long, without

abscission zone, terete, not swollen, not deflexed in age, with a variable indumentum composed by uncinat, antrorse, eglandular hairs 0.1-0.2 mm long and, usually, scattered, patent, glandular hairs 0.3-1.5 mm long; stipules (2.3)3.3-4.2(6.5) mm long, 1.3-3.4 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on the abaxial surface and margin, glabrous adaxially. *Inflorescence* a dichasial cyme; cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 1-2.8]; peduncles (2.5)13-32(90) mm long, with uncinat, antrorse, eglandular hairs 0.2-0.3 mm long and, usually, patent, glandular hairs 0.3-0.9 mm long; bracteoles 1.2-4.2 mm long, 0.7-2 mm wide, lanceolate, obtuse, whorled; pedicels absent or (2.5)6.5-11.2(18) mm long, with uncinat, antrorse, eglandular hairs 0.1-0.3 mm long and, usually, patent, glandular hairs 0.3-0.6 mm long. Flowers zygomorphic. *Sepals* (6.4)6.8-8.2(8.5) mm long, 2.8-5.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (1.4)2-3.2(4.2) mm long [ratio mucro length/sepal length = (0.22)0.29-0.34(0.46)], with uncinat, eglandular hairs 0.1-0.3 mm long and ± scattered, patent, glandular hairs 0.2-1.2 mm long on the abaxial surface, glabrous adaxially. *Petals* (10)13.3-14.7(16.7) mm long, (5.1)7.1-7.9(9.3) mm wide, patent, rounded, with claw 3.7-6.9 mm long, purple, hairy on the base on both adaxial and abaxial surface, ciliate on the basal margin, with hairs 0.2-0.4 mm long. *Stamens* 10, both whorls bearing anthers; filaments (15)16.8-19.9(21) mm long, linear-lanceolate, sometimes with a pair of teeth very near the base, purple, glabrous or with some cilia 0.2-0.3 mm long on the base; anthers (1.7)1.9-2.1(2.5) mm long, reddish. Nectaries 5, hemispheric, glabrous. *Gynoecium* 16-33 mm long, red. *Fruit* (33)37-44(49) mm long, erect, discharge of carpel-projection type, operative; mericarps 2.2-3.2 mm long, 1-1.6 mm wide, without a strand of fibers, not compressed

at the apex, reticulate, with the thin transversal ridges weakly branched, without basal beak, without a basal callus, without a basal prong, brown, glabrous; rostrum 27-42 mm long, with a narrowed apex 13-26 mm long, not twisted, with patent, eglandular hairs 0.1-0.3 mm long and, rarely, patent, glandular hairs 0.1-0.2 mm long restricted to the basal half of the narrowed apex; stigmatic remnants 1.3-2.2 mm long, with 5 glabrous lobes. *Seeds* 2-2.7 mm long, 1.1-1.5 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons with entire margin. Figs. 776, 777.

*Pollen*. *Geranium*-type (Aedo 2017: 412; Bortenschlager 1967: 425; Gagnepain 1903: 86; Stafford & Blackmore 1991: 68).

*Chromosome number*.  $2n = 46$ , ca. 46, 87-93, 92.

*Phenology*. Collected in flower from April to September.

*Distribution*. This species ranges from southern France to Bulgaria and Greece and it is introduced in Belgium, Germany, Great Britain, Canada and U.S.A. (Fig. 778).

*Habitat*. Rocky ledges, open forests, and meadows, on limestones, serpentines or siliceous soils; 50-2850 m.

*Representative specimens examined*.

**Discussion.** *Geranium macrorrhizum* is a perennial herb with a robust, more or less horizontal rootstock that shows some stipules and the petiole base. The aerial stem has quite a long naked portion up to the inflorescence. The inflorescence has one or two nodes with a pair of opposite leaves, the first shortly petiolate and the second almost sessile. The groups of 2-flowered cymules at the end of each branch can be distinct, that is, with well-developed peduncles, or with short or null pedicels and in umbel-like aggregates. The flowers are modified, being horizontal at anthesis and zygomorphic. The petals have a distinct, smooth claw, without the double keel of species of section *Ruberta*. The stamens are a bit shorter than the petals, but they seem exerted because the petal blade is spread. Staminal filaments are displaced to the lower side of the flower and slightly turned up at the tips and the style is displaced and curved like the stamens. The staminal filaments are linear-lanceolate, with an expanded base usually with some cilia. When the fruit is still immature, the staminal filaments remain appressed to the rostrum, protruding from the sepals. The indumentum, which consists of glandular and eglandular, usually uncinat, hairs, varies considerably. In some individuals, one of the two types of hairs is almost completely lacking. The density of glandular and eglandular hairs varies sometimes on the same sheet.

*Geranium macrorrhizum* is quite similar to *G. dalmaticum* in general appearance and inflorescence structure. Both species share zygomorphic flowers, exerted staminal filaments, fruit rostrum with a long, narrowed apex, and reticulate mericarps. Leaves of *G. macrorrhizum* are longer than those in *G. dalmaticum* and with more lobes per segment, even in small individuals. Additionally, *G. macrorrhizum* has a sepal mucro noticeably longer than

that of *G. dalmaticum*. The stamens have an expanded, triangular base that abruptly narrows into the linear staminal filaments. In some rare individuals the expanded base has a pair of auricles, one on each side, as in *G. dalmaticum*. Although with some overlap, bracteoles, sepals, and staminal filaments are longer in *G. macrorrhizum* than in *G. dalmaticum*.

Șerbănescu (1942) analyzed the variability of *Geranium macrorrhizum* and proposed a division of this species in six varieties and three additional forms. The basis of these groups is the degree of division of the leaves and the variation of the indumentum. These features are highly variable, however, even within the same gathering, which advises against its taxonomic use. Unfortunately, some of the types of these names remain unknown. Tan & al. (2011) described *G. kikianum*, a new species endemic to the Taigetos Mountains in the Peloponnese. It is differentiated by its narrow petals (5.5-7 mm wide) in contrast to those of *G. macrorrhizum* (11-14 mm wide), with a narrow claw. I have found great variation in petal size in *G. macrorrhizum* across its area, which suggests that *G. kikianum* may be a local variation without taxonomic significance. Wagensommer & Venanzoni (2021) described *G. lucarinii*, as a closely related species to *G. macrorrhizum*, based on its longer peduncles, pedicels and sepal mucro and the persistence of basal leaves with segments that often overlapping on the margin. All these characters fall into the variability of *G. macrorrhizum* and thus *G. lucarinii* is here considered conspecific. When Stefanoff & Jordanov (1931) described *Geranium macrorrhizum* var. *kellereri*, they indicated that the original material was collected in "Juni 1927." The date of the lectotype is not exactly as it is in the protologue (21 June 1926), which may be an erratum.

García-Aloy & al. (2017, table S8) recorded *G. macrorrhizum* from "France, Pyrenees; Aldasoro s.n."; so far no herbarium voucher has been found for this amazing locality.

**307. *Geranium dalmaticum* (Beck)**

Rech. f., Magyar Bot. Lapok 33: 28. 1934. *Geranium macrorrhizum* var. *dalmaticum* Beck, Verh. K.K. Zool.-Bot. Ges. Wien 46: 266. 1896. *Geranium macrorrhizum* [B] *dalmaticum* (Beck) Graebn. in Asch. & Graebn., Syn. Mit-

teleur. Fl. 7(1): 58. 1913. TYPE LOCALITY: "Dalmatia: In monte Vipera penninsulae Sabioncello in fissuris et glareis rupium calcearum altid. 700-850 m s.m. Florens legit mens. Junio 1894 G. de Beck". TYPE: Croatia. Dalmatia, Sabioncello, monte Vipera, 42°59'N, 17°10'E, 12 June 1894, G. Beck s.n. (lec-

totype, designated by Aedo 2017b: 449, PRC-450807 image!).

*Geranium macrorrhizum* subsp. *microrrhizum* Freyn, Mém. Herb. Boissier 13: 4. 1900, ["microrrhizon"]. *Geranium microrrhizum* (Freyn) O. Schwarz, Repert. Spec. Nov. Regni Veg. 40: 352. 1936. TYPE LOCALITY: "Dalmatia australis, Ragusa: in cacumine montis dicto Monte Vipere 960 m supra mare dia 18. Julio 1899 leg. Brandis". TYPE: Croatia. Dalmatia, Ragusa, monte Vipera, 42°59'N, 17°10'E, 18 July 1899, E.S.J. Brandis s.n. (lectotype, designated by Aedo 2017b: 450, BRNM image!).

Fig. 779. *Geranium dalmaticum*. a. Habit. b. Detail of the leaf insertion on the stem. c. Leaf. d. Stipules. e. Bracteoles. f. Flower. g. Sepal. h. Petal. i. Stamen. j. Fruit. k, l. Mericarps. m. Seed. (Based on: a-g, j-m, Baldacci 110, BM; h, i, Alanko 1359, H).

*Perennial herbs*, 8-23 cm tall. *Rootstock* 2.7-4.3 mm in diameter,  $\pm$  horizontal, not tuberculate, not turnip-shaped, without thickened roots. *Stem* erect, leafy or scapiform, not rooting at nodes, stolons absent, without vegetative stems, with abundant uncinat, eglandular hairs 0.1-0.2 mm long and, sometimes, scattered, patent, glandular hairs 0.1-0.2 mm long. *Basal leaves* in a persistent rosette, cauline leaves usually absent, sometimes 1 pair of small, opposite leaves; leaf laminae (2)2.1-3.2(3.6) cm long, 2.2-4.2 cm wide, not peltate, palmatifid [ratio main-sinus length/middle segment length = (0.78)0.82-0.86(0.88)], polygonal in outline, base cordate, not coriaceous, with nerves not projected, with uncinat, eglandular hairs on nerves of the adaxial surface and margin, glabrous or with scattered eglandular hairs abaxially; segments 5, in 1 plane, middle segment rhombic, 1.6-5.4 mm wide at the base [ratio segment width at the base/middle segment length = (0.13)0.15-0.21(0.22)], 3-5(6)-lobed in distal half [ratio secondary sinus length/middle segment length = (0.15)0.21-0.25(0.26)]; petioles up to 13 cm long, without abscission zone, terete, not swollen, not deflexed in age, with uncinat, antrorse, eglandular hairs 0.1-0.3 mm long; stipules (2.2)2.4-3.9(4.8) mm long, 0.7-1.5 mm wide, lanceolate, free, papery, brownish red, with eglandular hairs on the abaxial surface and margin, glabrous adaxially. *Inflorescence* a dichasial cyme;

cymules 2-flowered, solitary or in aggregates at the top of each branch [ratio cymule length/leaf length = 0.4-6.6]; peduncles 2.2-16(98) mm long, with uncinata, antrorse, eglandular hairs 0.1-0.2 mm long and sometimes patent, glandular hairs 0.3-0.4 mm long; bracteoles 1-1.8 mm long, 0.5-0.8 mm wide, lanceolate, obtuse, whorled; pedicels (2.5)5.1-7.6(9.2) mm long, with uncinata, antrorse, eglandular hairs 0.1-0.3 mm long and, usually, patent, glandular hairs 0.3-0.5 mm long. Flowers zygomorphic. *Sepals* (5.5)6-6.6(7.3) mm long, 3-4.3 mm wide, lanceolate, smooth, not accrescent, nerves 3, mucro (0.9)1.1-1.6(1.7) mm long [ratio mucro length/sepal length = (0.16)0.20-0.22(0.31)], with uncinata, eglandular hairs 0.2-0.3 mm long and  $\pm$  patent, glandular hairs 0.5-1.9 mm long on the abaxial surface, glabrous adaxially. *Petals* (12.4)14-16.7(18.1) mm long, (7.7)9.3-12.2(13.8) mm wide, patent, rounded, with claw 3.4-6.7 mm long, purple, hairy on the base on both adaxial and abaxial surface, ciliate on the basal margin, with hairs 0.2-0.6 mm long. *Stamens* 10, both whorls bearing anthers; filaments (10.8)13.9-15(16.5) mm long, linear-lanceolate, with a pair of teeth very near the base, pink, glabrous except on the basal teeth, with hairs 0.2-0.6 mm long; anthers 1.7-1.9(2) mm long, reddish. Nectaries 5, hemispheric, glabrous. *Gynoecium* 11-24 mm long, red. *Fruit* 31-45 mm long, erect, discharge of carpel-projection type, operative; mericarps 2.6-3.4 mm long, 1.2-1.3 mm wide, without a strand of fibers, not compressed at the apex, reticulate, with thin transversal ridges slanting and occasionally forking or merging, without basal beak, without a basal callus, without a basal prong, brown, glabrous; rostrum 26-38 mm long, with a narrowed apex 14-15.8 mm long, not twisted, with patent, eglandular hairs 0.1-0.2 mm long and, sometimes, patent, glandular hairs 0.1-0.2 mm long restricted to the basal half of the narrowed apex; stigmatic rem-

nants 1.4-2 mm long, with 5 glabrous lobes. *Seeds* 2-2.2 mm long, 0.9-1.3 mm wide, finely reticulate, uniformly colored, brown, glabrous. Cotyledons not studied. Fig. 779.

*Pollen*. *Geranium*-type (Aedo 2017: 412).

*Chromosome number*.  $2n = 46$ .

*Phenology*. Collected in flower from May to August.

*Distribution*. This species ranges from southern Croatia to Montenegro and northern Albania and it is occasionally introduced in northwestern U.S.A. (Fig. 780).

*Habitat*. Fissures, crevices and screes of limestone rocks; 300-950 m.

*Additional specimens examined*. **Albania**. SHKODËR: Skala Rapsa, Holti, 42°24'N, 19°29'E, 26 June 1900, *Baldacci* 8 (M, W); Skala Rapsa, Holti, 42°24'N, 19°29'E, 26 June 1900, *Baldacci* s.n. *Discussion*. *Geranium dalmaticum* is a small perennial herb with a more or less horizontal and branched rootstock. The aerial stem is usually naked except for a pair of leaves below the inflorescence. Sometimes these leaves are just vestigial, giving the appearance of a subscapose habit. In well-developed individuals,

Fig. 780. Distribution of *Geranium dalmaticum*.

the inflorescence comprises three 2-flowered cymules arranged dichasially. In contrast, in other specimens the inflorescence may be reduced to a single 2-flowered cymule. Bracteoles are usually arranged on the junction of the peduncle and pedicel, but sometimes some supplementary bracteoles can be found on the pedicel. The flowers are zygomorphic, like those of *G. macrorrhizum*. The staminal filaments are linear-lanceolate, with an expanded base that has hairy-tipped auricles on each side. These auricles have been found in all individuals examined.

*Geranium dalmaticum* is an endemic restricted to a few localities in southern Croatia, Montenegro, and northern Albania. It seems that in this area there are no collections of *G. macrorrhizum*. The differences between *G. macrorrhizum* and *G. dalmaticum* are indicated under *G. macrorrhizum*. Since most of these differences are related to size, *G. dalmaticum* could simply be considered a reduced form of *G. macrorrhizum*. However, its geographic isolation as well as the fact that these differences are maintained in cultivation, strongly support its recognition as an independent species.

*Geranium dalmaticum* is used occasionally in gardens and recently found, probably not well-established yet, in northwestern U.S.A.

## MISCELLANEOUS DOUBTFUL AND NOT VALIDLY PUBLISHED NAMES

Between square brackets is indicated the name of the taxa which is usually attributed the name, if possible. Between brackets are indicated the articles of the Shenzhen Code, if necessary.

- Geranium* sect. *Batrachia* L., in Murray, Syst. Veg. ed. 13: 513. 1774. nom. inval., includes the type of the name of the genus but does not repeat the generic name (art. 22.2).
- Geranium* sect. *Batrachia* W.D.J. Koch, Syn. Fl. Germ. Helv. 1: 137. 1835. nom. inval., includes the type of the name of the genus but does not repeat the generic name (art. 22.2).
- Geranium* sect. *Eugeranium* Godr. in Gren. & Godr., Fl. France 1: 297. 1847, nom. inval., because the use of the prefix *Eu* (art. 21.3).
- Geranium* sect. *Geranotypus* Dumort., Fl. Belg.: 112. 1827, nom. inval., includes the type of the name of the genus but does not repeat the generic name (art. 22.2).

- Geranium caespitosum* var. *eremophilum* (Wooton & Standl.) W.C. Martin & C.R. Hutchins, Fl. New Mexico 1: 1121. 1980, nom. inval., combination proposed without reference to basionym (art. 41.5) [*G. caespitosum*].
- Geranium caespitosum* var. *fremontii* (Torr. ex A. Gray) Dorn, Vasc. Pl. Wyoming: 180, 304. 1988, nom. inval., combination proposed without reference to basionym (art. 41.5) [*G. caespitosum*].
- Geranium caffroides* R. Knuth, Bot. Jahrb. Syst. 32: 214. 1903, nom. nud. [*G. incanum*].
- Geranium calabricum*, nom. nud., in sched. (K!) [*G. asphodeloides*].
- Geranium calabrum* Ten., nom. nud., in sched. (NAP!) [*G. molle*].
- Geranium camaense* C.C. Huang in C. Y. Wu, Fl. Xizangica 3: 10. 1986, nom. inval., without type (art. 40.1).
- Geranium camaense* C.C. Huang in S. Y. Jin, Cat. Type Spec. Herb. China: 301. 1994. TYPE LOCALITY: "Xizang: Dinggyê, Cama River, alt. 4000m, in slip of rock". TYPE: CHINA. Xizang, Dinggyê, Cama River, 28°18'N, 88°06'E, Pu 826 (holotype, PE). This species is only known from the type collected in Xizang (Dinggye Xian). According to the original description, it is similar to *G. lucidum* L. (subg. *Robertium*) but differs in having leaves and flowers glabrous. *Geranium lucidum* is a European species that reaches the W Himalayas and Nepal. It is an annual and very easy to recognize by its calyx with lengthwise keels and transverse flaps between these. Unfortunately, it has not been possible to examine the type specimen of *G. camaense*.
- Geranium campestre* Schangin in Pall., Neueste Nord. Beytr. Phys. Geogr. Erd-Völkerbeschreib. 6: 112. 1793, nom. nud. [*G. pseudosibiricum*].
- Geranium carmineum* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 119. 1912. TYPE LOCALITY: "Mexiko: Prov. Oaxaca, im Distrikt Nochistlan bei Cuauhtlilla (C. u. Ed. Seler, Pl. mexic. a. 1895 n. 1517 sub nom. *G. Hernandezii* DC. vel aff.? in Bull. Herb. Boiss. 2. Ser. III. [1903] 94!; bei San Miguel Quilitongo (C. et Ed. Seler, Pl. mexic. a. 1895 n. 1448! sub nom. *G. mexicanum* H.B.K. p.p. in Bull. Herb. Boiss. 2. Ser. III (1903) 94). Ohne Standortsangabe (Uhde n. 1190!). — Blühend und fruchtend November". SYNTYPES: Mexico. Oaxaca, im Distrikt Nochistlan bei Cuauhtlilla, 17°28'N, 97°14'W, 1895, C. Seler & E. Seler 1517 (no original material located); San Miguel Quilitongo, 17°27'N, 97°10'W, 1895, C. Seler & E. Seler 1448 (no original material located); unknown locality, C.A. Uhde 1190 (no original material located). The original description of *G. carmineum* fits well with *G. seemannii*; however, no original material of *G. carmineum* has been located, and the name cannot be fixed with certainty. Moore (1943: 103) also considered *G. carmineum* as a "doubtful" name.
- Geranium carolinianum* var. *lanuginosum* Nicolas, nom. nud., in sched. (K!) [*G. seemannii* subsp. *seemannii*].
- Geranium carolinum* Burm. f., Spec. Bot. Geran.: 27. 1759, [var. ortho., recorded

in Knuth's (1912) monograph & IPNI] [*G. carolinianum*].

*Geranium combretii* Ludlow & Sherriff, nom. nud., in sched. (BM!).

*Geranium compar* R. Br. in Salt, Voy. Abyss.: lxv. 1814, nom. nud., in sched. (BM!) [*G. arabicum*].

*Geranium core* Kostel., Allg. Med.-Pharm. Fl.: 1900. 1836. TYPE LOCALITY: "Feuill. 3. t. 16) eine in Chili...". TYPE: Feuillée, Journal des Observations Physiques, Mathématiques et Botaniques 3: tab. 16. 1725 (lectotype, designated by Aedo 2012: 446).

Knuth (1912) considered *G. core* a synonym of *G. rotundifolium* L. Dr. J. Hadinec kindly searched Kosteletzky's herbarium material of *Geranium* and informed me that there is no specimen at PRC that could serve as type material of *G. core* Kostel. The name is not listed in the first list of PRC holdings prepared after incorporation of Kosteletzky's herbarium. Thus, the drawing by Feuillée remains the only original element. This drawing shows a perennial species with a turnip-shaped rootstock that may be related to species allied with *G. berterioanum*; however, there is no other character that permits determination to species.

*Geranium cucullatum* var. *typicum* R. Knuth, Bot. Jahrb. Syst. 37: 568. 1906, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. sibbaldioides*].

*Geranium cuneatum* var. "*sinclair*" R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 217. 1912, nom. nud., pro syn. [*G. hillebrandii*].

*Geranium cuneatum* var. *hillebrandii* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 217. 1912, nom. nud. [*G. hillebrandii*].

*Geranium dahuricum* var. *alpinum* Bar. & Skv. in Liou & al., Clav. Pl. Chin. Bor.-orient.: 196. 1959, nom. inval., without Latin description (art. 39.1) [*G. dahuricum*].

*Geranium declinatum* Moench, Suppl. Meth.: 97. 1802. TYPE LOCALITY: [not indicated]. TYPE: Unknown locality and collector (no original material located). According to Stafleu & Cowan (1981: 536) the herbarium and types no longer extant.

*Geranium diffusum* Picard ex B.D. Jacks., Index Kew. 2: 1019. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. columbinum*].

*Geranium diffusum* var. *genuinum* Briq., Annuaire Conserv. Jard. Bot. Genève 11-12: 189. 1908, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. diffusum*].

*Geranium diffusum* var. *grandiflorum* Hieron. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 211. 1912, nom. nud., pro syn. [*G. diffusum*].

*Geranium dissectum* Gay ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 71. 1912, nom. nud., pro syn. [*G. berterioanum*].

*Geranium donianum* Wall. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 185. 1912, nom. nud., pro syn. [*G. collinum*].

*Geranium durangensis* Rose ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 201. 1912, nom. nud. [*G. wislizeni*].

*Geranium durieui* Spach, nom. nud., in sched. (LE!) [*G. rotundifolium*].

*Geranium eginense* Hausskn. & Sint. ex R. Knuth, Bot. Jahrb. Syst. 32: 217. 1903, nom. nud. [*G. purpureum*].

*Geranium ehrenbergianum* Schltdl. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 171, 620. 1912, nom. nud. [*G. bellum*].

*Geranium elatum* Picard ex B.D. Jacks., Index Kew. 2: 1019. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. pusillum*].

*Geranium emirnense* Hils. & Bojer, J. Proc. Linn. Soc., Bot. 6: 6. 1862, nom. nud., pro syn. [*G. arabicum*].

*Geranium emirnense* Hils. & Bojer ex Hook. f., J. Proc. Linn. Soc., Bot. 7: 185. 1864, nom. nud., pro syn. [*G. arabicum*].

*Geranium erectum* Trautv. ex Regel, Trudy Imp. S.-Peterburgsk. Bot. Sada 5: 253. 1877, ortho. mistake; according to Bobrov (1949: 30): "calami lapsu" [*G. rectum*].

*Geranium erianthum* A. Gray ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 181. 1912, nom. nud., pro syn. [*G. yesoense*].

*Geranium erianthum* Lindl. ex B.D. Jacks., Index Kew. 2: 1029. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. oreganum*].

*Geranium erianthum* Torr. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 117. 1912, nom. nud., pro syn. [*G. oreganum*].

*Geranium erianthum* f. *communis* Kom., Fl. Kamtschatka 2: 294. 1929, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. erianthum*].

*Geranium erianthum* f. *pallescens* Nakai, Tennenkinenbutsu Chosa Hokoku 12: 50 (1930), nom. nud. [*G. erianthum*].

*Geranium eriostemon* D. Don ex B.D. Jacks., Index Kew. 2: 1019. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. lambertii*].

*Geranium eriostemon* var. *pallidum* Sweet, Geraniaceae 2, tab. 197b. 1824. *Geranium pallidum* (Sweet) Steud., Nomencl. Bot. ed. 2, 1: 679. 1840, nom. inval., not accepted by its author (art. 36.1). TYPE LOCALITY: "About the same

time we received a plant in fine flower from Sir R.C. Hoare, who informed us that he had raised it from seeds given him by A.B. Lambert, Esq. but he knew not from whence they procured... From the habit of the plant we suspected it to be a native of Nepal; and we have since been informed by Mr. D. Don that it is a native of that country, and specimens of it are preserved in Mr. Lambert's Herbarium". TYPE: NEPAL? A.B. Lambert s.n. (no original material located).

The illustration mentioned in the protologue is a simple detail of a flower which is not enough to clarify the identity of this name. According to Sweet (1824) the plant was raised from seed given by Lambert, probably from Nepal.

*Geranium eritreae* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 61. 1912. TYPE LOCALITY: "Eritrea: Schlucht von Gua bei Saganeiti (Schweinfurth, Col. Eritr. a. 1892, n. 1276!)" TYPE: Eritrea. Schlucht von Gua bei Saganeiti, 15°03'N, 39°11'E, 1892, G.A. Schweinfurth 1276 (no original material located).

Kokwaro (1971a: 649) indicated that he was not able to locate the type (or any other material) of *G. eritreae* in the following herbaria: BM, BR, EA, FI, K, KAW, LD, LINN, MHU, O, P, S, and UPS. Additionally, a search in B, C, E, G, L, LE, M, NY, US, W, and WU has also been negative. It is probable that it was lost during the destruction of the Berlin Herbarium during World War II. Kokwaro (1971a) suggested that *G. eritreae* may be a synonym of *G. favosum*. Gilbert & Voster (2000) considered that the description of the mericarps fits those of *G. favosum* or *G. mascatense* but the leaves are more comparable to those of *G. favosum*.

*Geranium erlangerianum* Engl. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 206. 1912, nom. nud., pro syn. [*G. arabicum*].

*Geranium escalonense* R. Knuth, Repert. Spec. Nov. Regni Veg. 34: 145. 1933. TYPE LOCALITY: "Bolivia: Cuesta del Escalon, Matten, 2900 m (Troll a. 1927 n. 485 — Typus in herb. Berol.). — Blühend November". TYPE: Bolivia. Chuquisaca, Cuesta del Escalón, 19°28'S, 64°11'W, 1927, C. Troll 485 (holotype, B destroyed).

The original description fits well with *G. rupicola*, except for the 2-flowered cymules. No duplicates of the holotype were located, but two specimens of Troll 484 were found. Both were collected in "Cuesta del Escalon", but have 1-flowered cymules. The label of the specimen at B gives the date "24.11.1927" and the altitude "2900 m"; on the label of the

duplicate at JE the date is "29.11.1927" and the altitude "2200 m." Because the specimen at B lacks Knuth's annotation label, it is likely that it was acquired after the destruction of the Berlin Herbarium during World War II and not seen by Knuth.

*Geranium europaeum* Popov ex Bobrov in Kom. & al., Fl. URSS 14: 59. 1949, nom. nud. [*G. sibiricum*].

*Geranium exile* Standl. ex R. Knuth, Repert. Spec. Nov. Regni Veg. 40: 220. 1936, nom. nud., pro syn. [*G. azurelloides*].

*Geranium fagrigii* W.M. Brooke, nom. nud., in sched. (BM!).

*Geranium flexuosum* E. Mey. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 165. 1912, nom. nud., pro syn. [*G. baurianum*].

*Geranium foetidum* Gilib., Fl. Lit. Inch. 2: 178. 1782, ["faetidum"], nom. inval., suppressed work (art. 34.1) [*G. robertianum*].

*Geranium forsan* Hohen., Enum. Pl. Talysh: 158. 1838, nom. inval., sine descr. (art. 38.1).

*Geranium fremontii* Macoun ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 117. 1912, nom. nud., pro syn. [*G. oreganum*].

*Geranium frigidum* Hochst. ex A. Rich., Tent. Fl. Abyss. 1: 116. 1847, nom. nud., pro syn. [*G. arabicum*].

*Geranium furcatum* Kanitz, Linnaea 32: 567. 1864, nom. inval., not accepted by its author (art. 36.1).

*Geranium furcatum* Schur ex B.D. Jacks., Index Kew. 2: 1020. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. dissectum*].

*Geranium fusiforme* Yeo, Edinburgh J. Bot. 49(2): 155. 1992, nom. nud., pro syn. [*G. rosthornii*].

*Geranium gardi* Sennen, nom. nud., in sched. (BC!) [*G. robertianum*].

*Geranium geissei* R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 70. 1912. TYPE LOCALITY: "Chile: Ohne genauere Standortangabe (Geisse — Typus in herb. Berol.)". TYPE: Chile. [without locality], R. Geisse s.n. (holotype, B destroyed; photos, FI, GI, GHI, NY!).

The holotype is no longer extant, and no duplicates were located. None of the Geisse collections at SGO can be associated with this name. The photographs of the holotype are not sufficiently detailed to permit accurate identification, but suggest that the name may be a synonym of *G. berterioanum*.

*Geranium geminatum* Ehrenb. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 97 (1912), nom. nud., in sched. [*G. tuberosum*].

*Geranium gerardi* André, Rev. Hort. ser. 4, 63: 350. 1891, nom. nud. [*G. psilostemon*].

- Geranium molle* [f.] *glabrata* A. Terracc., Malpighia 4: 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [f.] *pygmaea* A. Terracc., Malpighia 4: 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [f.] *sepincola* A. Terracc., Malpighia 4: 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [f.] *tenuisecta* A. Terracc., Malpighia 4: 199-200, 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [f.] *trivialis* A. Terracc., Malpighia 4: 199-200, 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [f.] *villosissima* A. Terracc., Malpighia 4: 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [subf.] *abortiva* (De Not. ex Ces.) A. Terracc., Malpighia 4: 202. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. molle*].
- Geranium molle* [a] *triviale* A. Terracc. ex Gortani & M. Gortani, Fl. Friulana 2: 300. 1906, nom. nud. [*G. molle*].
- Geranium montanum* J.F. Gmel. ex B.D. Jacks., Index Kew. 2: 1020. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. ibericum*].
- Geranium montanum* J. König ex O. Müll., Nova Acta Phys.-Med. Acad. Caes. Leop.-Carol. Nat. Cur. 4: 209. 1770, nom. nud.
- Geranium montanum* Pourret, nom. nud., in sched. (MAF-Pourret!) [*G. dolomiticum*].
- Geranium moranense* Benth., nom. nud., in sched. (W!) [*G. seemannii* subsp. *seemannii*]. I have found no connection between this name and *Erodium moranense* Willd. ex Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 5: 229. 1822, which is a heterotypic synonym of *E. cicutarium* (L.) L'Hér. ex Aiton.
- Geranium mosquense* Goldb. ex B.D. Jacks., Index Kew. 2: 1020. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. robertianum*].
- Geranium multiceps* var. *fimbriosum* Vareschi, nom. nud., in sched. (VEN-32447!) [*G. multiceps*].
- Geranium multiceps* var. *glabrum* Vareschi, nom. nud., in sched. (VEN-102088!) [*G. multiceps*].
- Geranium multiceps* var. *pilosum* Vareschi, nom. nud., in sched. (VEN-5318!) [*G. multiceps*].
- Geranium multiflorum* Lang ex Schur, Oesterr. Bot. Z. 18: 317. 1868, nom. nud., pro syn. [*G. pusillum*].
- Geranium multiflorum* var. *typicum* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 219. 1912, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. multiflorum*].
- Geranium multipartitum* var. *typicum* R. Knuth, Bot. Jahrb. Syst. 37: 566. 1906, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. humboldtii*].
- Geranium nanum* Coss., nom. nud., in sched. (BR-0000013347079 image!, FI!, G-00018762!, K-000417201!, LE!, MPU-009258!, P-00084486!, Z) [*G. nanum*].
- Geranium napellifolium* Schur, Enum. Pl. Transsilv.: 136. 1866, nom. nud., pro syn. [*G. pratense*].
- Geranium nasirii* Y.J. Nasir, Pakistan J. Bot. 14(Abs.): 46. 1982, nom. nud.
- Geranium navieri* Jord. ex Gren., nom. nud., in sched. (P!) [*G. dissectum*].
- Geranium nebrodense* Tineo, nom. nud., in sched. (RO!) [*G. pyrenaicum* subsp. *pyrenaicum*].
- Geranium neesianum* Carolin in Jessop, List Vasc. Pl. South Australia: 35. 1983, nom. nud. [*G. retrorsum*].
- Geranium nemorale* var. *bicknellii* (Britton) Fernald, Rhodora 43: 35. 1941, comb. superfl., includes the type of a name that ought to have been adopted under

the rules (art. 52.1), but it has a basionym (art. 52.4) [*G. bicknellii*].

*Geranium neopumilum* Aedo & Muñoz Garm., Kew Bull. 52(3): 726. 1997. *Geranium pumilum* R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 88. 1912, non (Willd.) Poiret, 1812. TYPE LOCALITY: "Ecuador: Páramos del Cerro Antisana, 4056 m (Stuebel, Fl. Aeq. a. 1871 n. 185e — Typus in Herb. Berlin!). — Blüh. Oktober". TYPE: Ecuador. Pichincha, páramos del Cerro Antisana, 0°30'S, 78°10'W, 1871, A. Stuebel 185e (holotype, B destroyed).

The original description does not permit a conclusive interpretation of this taxon. The type was collected at the same locality as that of *G. antisanae*, and date and altitude are also the same. Knuth's description fits with *G. antisanae*, except for the glabrous leaves.

*Geranium neapolitanum* Nyman, Consp. Fl. Eur. Suppl. 1: 949. 1884, nom. nud., pro syn. [*G. pratense*].

*Geranium nepalense* f. *albiflora* T.H. Chung ex W.T. Lee, J. Korean Pl. Taxon. 12(2): 85. 1982, nom. inval., without type (art. 40.1) [*G. thunbergii*].

*Geranium neglectum* Kar. & Kir., nom. nud., in sched. (LE!) [*G. collinum*].

*Geranium nodosum* Eichw. ex R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 190. 1912, nom. nud., pro syn. [*G. gracile*].

*Geranium novum* Winterl, Index Hort. Bot. Univ. Hung. without page number, fig. 2. 1788, nom. inval., word not intended as a specific epithet (art. 23.6) [*G. divaricatum*].

*Geranium ocellatum* var. *angustisectum* Engl. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 207. 1912, nom. nud., pro syn., in sched. [*G. vagans*].

*Geranium occitanum* Batt. & Pit. in Pit., Contr. Fl. Atl.: 15. 1919, [var. ortho., recorded in the IPNI] [*G. cataractarum*].

*Geranium ornatum* A. Nelson ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 117. 1912, nom. nud., pro syn. [*G. viscosissimum*].

*Geranium pallidum* Royle in Hook. f., Fl. Brit. India 1: 431. 1874, nom. nud., pro syn. [*G. nepalense*].

*Geranium palmatum* Cav., Diss. 3: [186]. 1787, nom. nud. [Feb. 1787] [*G. palmatum*].

*Geranium palmatum* Picard ex B.D. Jacks., Index Kew. 2: 1020. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. dissectum*].

*Geranium palustre* Edgew. & Hook. f. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 128. 1912, nom. nud., pro syn. [*G. saxatile*].

*Geranium palustre* Thunb. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 192. 1912, nom. nud., pro syn. [*G. thunbergii*].

*Geranium palustre* var. *minus* Ledeb. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 176. 1912, nom. nud., pro syn. [*G. palustre*].

*Geranium panormitanum* Lojac., nom. nud., in sched. (FI!) [*G. molle*].

*Geranium partitum* Willd. ex Kunth in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 5: 231. 1822, nom. nud., pro syn. [*G. ayavacense*].

*Geranium parvulum* Ten. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 59. 1912, nom. nud. [*G. molle*].

*Geranium patens* Royle in Hook. f., Fl. Brit. India 1: 431. 1874, nom. nud., pro syn. [*G. nepalense*].

*Geranium patulum* Sol. in G. Forst., Fl. Ins. Austr.: 91. 1786, nom. nud. [*G. retrorsum*].

*Geranium pedatum* Raf., Herb. Raf.: 60. 1833, nom. nud.

*Geranium pedatum* Raf., New Fl. 2: 34. 1837. TYPE LOCALITY: "Glades and Prairies of West Kentucky and Illinois". TYPE: U.S.A. West Kentucky and Illinois (no original material located).

*Geranium pedunculatum* Royle, Ill. Bot. Himal. Mts.: 150. 1835, nom. inval., sine descr. (art. 38.1).

*Geranium perrugosum* Borbás ex Kanitz, Pl. Roman.: 28. 1879, nom. nud.

*Geranium persianum* Pau, nom. nud., in sched. (BC-12682!) [*G. mascatense*].

*Geranium persicum* Pau, nom. nud., in sched. (MA-71303!) [*G. mascatense*].

*Geranium phaeum* Sebast. & Mauri ex B.D. Jacks., Index Kew. 2: 1020. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. reflexum*].

*Geranium phaeum* Siev. ex B.D. Jacks., Index Kew. 2: 1020. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. platyanthum*].

*Geranium phaeum* subsp. *normale* A. Terracc., Malpighia 4: 219. 1890, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. phaeum*].

*Geranium phaeum* var. *vulgatius* DC., Prodr. 1: 641. 1824, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. phaeum*].

*Geranium phaeum* subvar. *genuinum* Rouy in Rouy & Foucaud, Fl. France 4: 82. 1897, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. phaeum*].

*Geranium phaeum* f. *austriacum* Wiesb., Natur Offenbarung 41: 636. 1895, nom. inval., not accepted by its author (art. 36.1) [*G. phaeum*].

*Geranium phaeum* f. *hungaricum* Wiesb., Natur Offenbarung 41: 636. 1895, nom.

inval., not accepted by its author (art. 36.1) [*G. phaeum*].

*Geranium phaeum* [f.] *baldensis* A. Terracc., Malpighia 4: 219. 1890, nom. nud. [*G. phaeum*].

*Geranium phaeum* [f.] *gallica* A. Terracc., Malpighia 4: 219. 1890, nom. nud. [*G. phaeum*].

*Geranium phaeum* [f.] *helvetica* A. Terracc., Malpighia 4: 219. 1890, nom. nud. [*G. phaeum*].

*Geranium phaeum* [f.] *pyrenaica* A. Terracc., Malpighia 4: 219. 1890, nom. nud. [*G. phaeum*].

*Geranium phaeum* [subf.] *fuscum* (L.) A. Terracc., Malpighia 4: 219. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. phaeum*].

*Geranium phaeum* [subf.] *patula* (Vill.) A. Terracc., Malpighia 4: 219. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. phaeum*].

*Geranium phaeum* [subf.] *planipetalum* (Chaix) A. Terracc., Malpighia 4: 219. 1890, nom. inval., the rank is denoted by a misplaced term (art. 37.6) [*G. phaeum*].

*Geranium phaeum* [\*] *lividum* (L'Hér.) Pers., Syn. Pl. 2: 235. 1806, nom. inval., see Greuter (1968: 92) [*G. phaeum*].

*Geranium pilgerianum* R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 106. 1912. TYPE LOCALITY: "Columbien, bei Cundinamarca: Páramo de Pasca, 3700-3800 m (Stuebel n. 146 p. p.)". TYPE: Colombia. Cundinamarca, Páramo de Pasca, 4°18'N, 74°18'W, A. Stuebel 146 p.p. (holotype, B destroyed; photos, FI, GI, GH!, NY!).

Neither the photograph of the type nor the original description permit a conclusive interpretation of this taxon; the two fragments shown in the photo do not display clearly the diagnostic inflorescence characters. No other collection from Páramo de Pasca seen during this study could be assigned to *G. pilgerianum*.

*Geranium pilosum* Sol. in G. Forst., Fl. Ins. Austr.: 91. 1786, nom. nud. [*G. solanderi*].

*Geranium pinetophilum* R. Knuth, Notizbl. Bot. Gart. Berlin-Dahlem 14: 352. 1939.

TYPE LOCALITY: "Nanga-Parbat-Gebiet, Rakhiot-Tal: Nadelwälder, den Unterwuchs, Beherrschend, 3300 m (blühend 29. Juni 1937 — C. Troll n. 7637, Typus!); Jalipur-Tal: Nadelwälder, 2800-3200 m (blühend 1. Juli 1937 — C. Troll n. 7678); Rupal-Tal: Tarshing, steinige Triften im bewässerten Land, 2900 m (blühend 11. Juni 1937 — C. Troll n. 7388)". TYPE: PAKISTAN. Nanga-Parbat-Gebiet, Rakhiot-Tal, 35°15'N, 74°35'E, 29 June 1937, C. Troll 7637 (holotype, B destroyed).

*Geranium pinnatifidum* Picard ex B.D. Jacks., Index Kew. 2: 1021. 1893, nom.

inval., not accepted by its author (art. 36.1) [*G. rotundifolium*].

*Geranium platypetalum* Fisch. & C.A. Mey. ex Hohen., Bull. Soc. Imp. Naturalistes Moscou 6: 246. 1833, nom. nud. [*G. platypetalum*].

*Geranium platyrenifolium* Z.M. Tan, Bull. Bot. Res., Harbin 6(2): 52, 61 tab. 4. 1986. TYPE LOCALITY: "Sichuan: Muli, Hetaowan, June 28, 1978, Muli Exped. 260 (Type, fl. ICD)". TYPE: CHINA. Sichuan, Muli, Hetaowan, 27°25'N, 102°30'E, 28 June 1978, Muli Exped. 260 (holotype, SM).

According to the original description this species has roots bearing one or two tubers at distances up to several cm from their origin, opposite leaves deeply divided, free stipules, cymules 2-flowered, petals 15-18 mm long with rounded apex and hairy base, and eglandular indumentum. It is found in meadows of SW Sichuan. Unfortunately, it has been not possible to examine any specimen belonging to this species.

*Geranium potentilloides* Bonpl. ex Wedd., Chlor. Andina 2: 284. 1861, nom. nud., pro syn. [*G. humboldtii*].

*Geranium potentilloides* Willd. ex Spreng., Syst. Veg. 3: 70. 1826, nom. nud., pro syn. [*G. humboldtii*].

*Geranium potentilloides* var. *alpestre* Ridl. in G.S. Hope, Equatorial Glaciers New Guinea: 161. 1976, nom. inval., combination proposed without reference to basionym (art. 41.5) [*G. papuanum*].

*Geranium praealpinum* Beck, Fl. Nieder-Österreich. 2: 560. 1892, nom. nud., pro syn. [*G. sylvaticum*].

*Geranium pratense* Jinuma ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 181. 1912, nom. nud., pro syn. [*G. soboliferum*].

*Geranium pratense* subsp. *stewartianum* Y.J. Nasir, Fl. Pakistan 149: 18 fig. 4, 19. 1983. *Geranium pratense* var. *stewartianum* Y.J. Nasir, Fl. Pakistan 149: 21. 1983. Type locality: "Tilel Vy., ± 9000', R.R. & I.D. Stewart 18569 (holo. RAW), as to left hand specimen only". Type: Pakistan. Tilel Vy., 35°36'N, 75°00'E, R.R. Stewart & I.D. Stewart 18569 (holotype, RAW, now at KUH, fragment image!).

The fragment examined does not permit a conclusive identification.

*Geranium pratense* subsp. *typicum* Woronow ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 128. 1912, nom. nud., pro syn. [*G. pratense*].

*Geranium pratense* var. *affine* (Ledeb.) C.C. Huang & L.R. Xu, Fl. Reipub. Pop. Sin. 43(1): 59. 1998, comb. superfl. [*G. pratense*].

*Geranium pratense* var. *albiflorum* Opiz, Seznam: 47. 1852, nom. nud. [*G. pratense*].

*Geranium pratense* var. *laciniatum* Ten., Index Sem. Hort. Bot. Neapol.: 4. 1825, nom. nud. [*G. pratense*].

*Geranium pratense* var. *napellifolium* Schur ex Nyman, Consp. Fl. Eur.: 137. 1878, nom. nud. [*G. pratense*].

*Geranium pratense* var. *parviflorum* Opiz, Seznam: 47. 1852, nom. nud. [*G. pratense*].

*Geranium pratense* var. *semiplenum* Lindm., Bot. Soc. Exch. Club Brit. Isles 7: 765. 1925, nom. nud. [*G. pratense*].

*Geranium pratense* var. *typicum* Krylov in Serg., Sist. Zametki Mater. Gerb. Krylova Tomsk. Gosud. Univ. Kujbyševa 1: 3. 1934, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. pratense*].

*Geranium pratense* f. *lanigera* Coste ex Sennen, Pl. Espagne 1916 n.° 2572. 1916, nom. nud., in sched. (BC-12444!, BM!, MA!, MAF-58797!, MAF-58795!) [*G. pratense*].

*Geranium proximum* Bertero ex Steud., Nomencl. Bot. ed. 2, 1: 679. 1840, nom. inval., without description (art. 38.1) [*G. berterooanum*].

*Geranium pseudosibiricum* Maxim. ex B.D. Jacks., Index Kew. 2: 1021. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. dahuricum*].

*Geranium pseudosibiricum* var. *typicum* Regel, Tent. Fl.-Ussur.: 41. 1861, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. pseudosibiricum* J. Mayer].

*Geranium pseudotuberosum* Boiss. & Reuter, nom. nud., in sched. (P!) [*G. malviflorum*].

*Geranium pseudovillosum* Schur, Enum. Pl. Transsilv. 921. 1866, ["pseudo-villosum"], nom. nud., pro syn. [*G. molle*].

*Geranium ptychocarpum* Hochst., nom. nud., in sched. (RO!, SI).

*Geranium pubescens* Willd. in Humb., Bonpl. & Kunth, Nov. Gen. Sp. 5: 231. 1822, nom. nud., pro syn. [*G. chilloense*].

*Geranium pumilum* R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 88. 1912, nom. illeg., non (Willd.) Poir. 1812. *Geranium neopumilum* Aedo & Muñoz Garm., Kew Bull. 52(3): 726. 1997. TYPE LOCALITY: "Ecuador: Páramos del Cerro Antisana, 4056 m (Stuebel, Fl. Aeq. a. 1871 n. 185e — Typus in Herb. Berlin!). — Blüh. Oktober". TYPE: Ecuador. Páramos del Cerro Antisana, 0°30'S, 78°10'W, 1871, A. Stuebel 185e (holotype, B destroyed).

The original description does not permit a conclusive interpretation of this taxon. The type was collected at the same locality as that of *G. antisanae*, and date and altitude are also the same. Knuth's

description fits with *G. antisanae*, except for the glabrous leaves.

*Geranium purpureum* Boucher ex R. Knuth in Engl., Pflanzenr. IV. 129 (Heft 53): 67. 1912, nom. nud., pro syn. [*G. purpureum*].

*Geranium purpureum* Gilib., Fl. Lit. Inch. 2: 175. 1782, nom. inval., suppressed work (art. 34.1) [*G. palustre*].

*Geranium purpureum* var. *genuinum* Rouy in Rouy & Foucaud, Fl. France 4: 97. 1897, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. purpureum*].

*Geranium purpureum* var. *minutiflorum* (Jord.) Rouy in Rouy & Foucaud, Fl. France 4: 98. 1897, comb. superfl. [*G. purpureum*].

*Geranium purpureum* var. *minutiflorum* (Jord.) Murb., Acta Univ. Lund. 27(5): 151. 1891, comb. superfl. [*G. purpureum*].

*Geranium purpureum* var. *modestum* (Jord. ex Fourr.) Rouy in Rouy & Foucaud, Fl. France 4: 97. 1897, comb. superfl. [*G. purpureum*].

*Geranium purpureo-caeruleum* Gilib. ex Ledeb., Fl. Ross. 1(2): 465. 1842, nom. nud., pro syn. sphalm. [*G. sylvaticum*].

*Geranium pusillum* A.M. Jiménez, Fl. Cochabamba: 178. 1984, nom. inval., without Latin description (art. 39.1).

*Geranium pusillum* Labram & Hegetschw. ex R. Knuth, Pflanzenr. IV.129 (Heft 53): 51. 1912, nom. nud., pro syn. [*G. dissectum*].

*Geranium pusillum* subsp. *normale* A. Terracc., Malpighia 4: 212. 1890, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. pusillum*].

*Geranium pusillum* var. *affine* Bertero ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 76. 1912, nom. inval., not accepted by its author (art. 36.1) [*G. core-core*].

*Geranium pusillum* var. *albiflorum* Opiz, Seznam: 47. 1852, nom. nud. [*G. pusillum*].

*Geranium rotundifolium* var. *viscosissimum* Heldreich, nom. nud., in sched. (BM!) [*G. rotundifolium*].

*Geranium rotundifolium* [a] *genuinum* Graebn. in Asch. & Graebn., Syn. Mitteleur. Fl. 7(1): 49. 1913, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. rotundifolium*].

*Geranium rotundifolium* f. *sennenii* Pau, nom. nud., in sched. (MA-71157!) [*G. rotundifolium*].

*Geranium rotundifolium* f. *umbellatum* R. Berger, Allg. Bot. Z. Syst. 20: 15. 1915, nom. nud. [*G. rotundifolium*].

*Geranium rubellum* Wender., Schriften Ges. Beförd. Gesamten Naturwiss. Marburg 2: 259. 1831, nom. illeg., non Moench 1802. TYPE LOCALITY: [not indicated]. TYPE: cultivated at Marburg botanical garden (no original material located). According to Stafleu & Cowan (1988: 178) Wenderoth's herbarium may be considered lost.

*Geranium rubescens* W.D. Jacks., Bol. Mus. Munic. Funchal 23: 31. 1969, nom. inval., pro syn. [*G. yeoi*].

*Geranium rupestre* Rafin., nom. nud., in sched. (P!) [*G. robertianum*].

*Geranium saltuense* Schldtl. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 101. 1912, nom. nud. [*G. crenatifolium*].

*Geranium sanguineum* var. *angustilobum* Sennen, Pl. Espagne 1921-23 n.º 4253. 1922, nom. nud., in sched. (BC!, BM!, MA-71570!, W!) [*G. sanguineum*].

*Geranium sanguineum* var. *asperifolium* Sennen, nom. nud., in sched. (BC-12374!) [*G. sanguineum*].

*Geranium sanguineum* var. *genuinum* Godr. in Gren. & Godr., Fl. France 1: 302. 1847, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. sanguineum*].

*Geranium sanguineum* var. *haematodes* Burm. f. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 139. 1912, nom. nud., pro syn. [*G. sanguineum*].

*Geranium sanguineum* var. *lancastriense* (Mill.) G. Nicholson, Ill. Dict. Gard. 2: 64. 1885, comb. superfl. [*G. sanguineum*].

*Geranium sanguineum* var. *majus* Maxim. ex Syr. & Petunn. in Syr., Ill. Fl. Mosk. Gub. 2: 326. 1907, nom. nud., pro syn. [*G. sanguineum*].

*Geranium sanguineum* var. *monstrosum* Scheppig ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 139. 1912, nom. nud. [*G. sanguineum*].

*Geranium sanguineum* var. *prostratum* (Cav.) Dum. Cours., Bot. Cult. 3: 6. 1802, comb. supefl. [*G. sanguineum*].

*Geranium sanguineum* var. *prostratum* (Cav.) Pers., Syn. Pl. 2: 234. 1806, comb. supefl. [*G. sanguineum*].

*Geranium sanguineum* var. *subnudicaulix*, nom. nud., in sched. (SOM!) [*G. sanguineum*].

*Geranium sanguineum* var. *vulgare* Čelak., Prodr. F. Böhmen 3: 530. 1875, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. sanguineum*].

*Geranium sanguineum* [b] *dubium* Rochel, Bot. Reise Banat: 55. 1838, nom. nud. [*G. sanguineum*].

*Geranium sanguineum* [c] *latilobum* Rochel, Bot. Reise Banat: 55. 1838, nom. nud. [*G. sanguineum*].

*Geranium scabiosiaefolium* J.F. Villiers, nom. nud., in sched. (P!) [*G. arabicum*].

*Geranium scopulicolum* Jord., nom. nud., in sched. (K!) [*G. purpureum*].

*Geranium semiorbiculare* Rchb., Fl. Germ. Excurs.: 778. 1832, nom. nud., pro syn. [*G. rotundifolium*].

*Geranium sennenii* Pau, nom. nud., in sched. (BC-825306!) [*G. rotundifolium*].

*Geranium sericeum* var. *typicum* Wedd. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 80. 1912, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. sericeum*].

*Geranium sessiliflorum* Cav., Diss. 3: [186]. 1787, nom. nud. [Feb. 1787] [*G. sessiliflorum*].

*Geranium sessiliflorum* var. *typicum* R. Knuth, Bot. Jahrb. Syst. 37: 565. 1906, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. sessiliflorum*].

*Geranium sessiliflorum* f. *albiflorum* Kuntze, Revis. Gen. Pl. 3(3): 33. 1898, nom. nud., in sched. (NY!) [*G. sessiliflorum*].

*Geranium sibiricum* Miq. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 192. 1912, nom. nud., pro syn. [*G. nepalense*].

*Geranium sibiricum* subsp. *eusibiricum* Gams in Hegi, Ill. Fl. Mitt.-Eur. 4(3): 1695. 1924, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. sibiricum*].

*Geranium solitarium* Z.M. Tan, Acta Phytotax. Sin. 33(6): 608, 609 fig. 1. 1995. TYPE LOCALITY: "Sichuan...: Pingwu..., Huya..., alt. 4500 m, 1978-07-21, Pingwu Exped. 636 (typus, SM)". TYPE: China. Sichuan, Pingwu, 32°24'N, 104°31'E, 21 July 1978, Pingwu Exped. 636 (holotype, SM). According to the original description, this species has roots long and thickened, opposite leaves not deeply divided, stipules distinct, cymules

1-flowered, petals ca. 1.8 cm, with rounded apex and basally with hairs, and eglandular indumentum. The fruit and seed are unknown. It is found in alpine habitats of N Sichuan. Unfortunately, it has not been possible to examine any specimens belonging to this species.

*Geranium somalense* Sprage, nom. nud., in sched. (K!) [*G. biuncinatum*].

*Geranium sonderianum* Turcz. ex Müll. Berol. in Walp., Ann. Bot. Syst. 7: 485. 1869, nom. nud. [*G. holosericeum*].

*Geranium sonorae* C.V. Morton, nom. nud., in sched. (NY!) [*G. charucanum*].

*Geranium stewartianum* Y.J. Nasir, Pakistan J. Bot. 14(Abs.): 46. 1982, nom. nud.

*Geranium stewartianum* subsp. *khillanmargensis* Y.J. Nasir, Pakistan J. Bot. 14(Abs.): 46. 1982, nom. nud.

*Geranium stewartianum* var. *chorwanianus* Y.J. Nasir, Pakistan J. Bot. 14(Abs.): 46. 1982, nom. nud.

*Geranium stewartianum* var. *schmidii* Y.J. Nasir, Pakistan J. Bot. 14(Abs.): 46. 1982, nom. nud. [*G. schmidii*].

*Geranium striatum* Clairv. ex B.D. Jacks., Index Kew. 2: 1021. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. rivulare*].

*Geranium strictipes* var. *grandiflorum* (Franch.) C.Y. Wu, Index Fl. Yunnan 1: 297. 1984, nom. inval., combination proposed without reference to basionym (art. 41.5) [*G. strictipes*].

*Geranium strictum* Picard ex B.D. Jacks., Index Kew. 2: 1021. 1893, nom. inval., not accepted by its author (art. 36.1) [*G. rotundifolium*].

*Geranium strobilii* Hay., nom. nud., in sched. (W!).

*Geranium subcaulescens* var. *genuinum* Boiss., Fl. Orient. 1: 872. 1867, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. subcaulescens*].

*Geranium subcaulescens* var. *palmatipartitum* Hausskn., nom. nud., in sched. [*G. palmatipartitum*].

*Geranium subcaulescens* f. *glabrescens* Boiss., Fl. Orient. Suppl.: 141. 1888, nom. nud. [*G. ponticum*].

*Geranium subcaulescens* f. *pallidiflora* Freyn ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 94. 1912, nom. nud. [*G. subacutum*].

*Geranium subcaulescens* f. *pallidiflora* Freyn, nom. nud., in sched. (BM!, EI, GI, JE!, LD!, LE!) [*G. subacutum*].

*Geranium subcaulescens* f. *purpureo-violacea* Freyn, nom. nud., in sched. (B!, BM!, EI, GI, JE!, LD!, LE!) [*G. subacutum*].

*Geranium subcaulescens* [ß] *parviflorum* Boiss., nom. nud., in sched. (BM!) [*G. subacutum*].

*Geranium subdivaricatum* Schur, Verh. Naturf. Vereins Brünn 15: 160. 1877, nom. inval., not accepted by its author (art. 36.1) [*G. divaricatum*].

- Geranium xinjiangense* C.Y. Yang, Claves Pl. Xinjiang. 3: 218. 1983, nom. inval., without Latin description (art. 39.1).
- Geranium yaanense* Z.M. Tan, Acta Phytotax. Sin. 33(6): 611, 610 fig. 2. 1995. TYPE LOCALITY: "Sichuan...: Yaan..., Xiatian..., alt. 1500 m, 1978-09-19, Yaan Exped. 1130 (typus, SM)". TYPE: CHINA. Sichuan, Yaan, Xiatian, 29°52'N, 102°12'E, 19 Sep. 1978, Yaan Exped. 1130 (holotype, SM). According to the original description, this species has opposite leaves not deeply divided, stipules distinct, cymes 2-flowered, petals ca. 9 mm, with rounded apex and basally with hairs, and glandular indumentum. It has been considered a synonym of *Geranium moupinense*, a species of the subg. *Robertium*. However, the latter has alternate leaves and reticulate mericarps. Unfortunately, it has not been possible to examine any specimens belonging to this species.
- Geranium yesoense* var. *genuina* Tatew., Trans. Sapporo Nat. Hist. Soc. 14: 263. 1936, nom. inval., epithet indicating the taxon containing the type of the name of the next higher-ranked taxon (art. 24.3) [*G. yesoense*].

## HYBRIDS

Hybridization experiments in *Geranium* have been carried out with species of subg. *Geranium* (Dahlgren 1923; Sansome 1936) and subg. *Robertium* (Van Loon 1984a; Wilder-Kiefer & Yeo 1987). Yeo (2002a: 38, 212) summarized the impressive work of artificial hybridisation carried out by Alan Bremmer, which otherwise remains unpublished, and provided a list of the hybrids that have flowered using the hybrid formulas.

In the following list I have compiled hybrids with a binomial name, that have been recorded in nature, have been found to grow spontaneously in gardens or have been artificially obtained. Exceptionally names with only hybrid formulas have been listed to discuss some different aspects.

### **G. argenteum × G. cinereum**

*Geranium × intermedium* Sünd., Allg. Bot. Z. Syst. 12: 91. 1906, nom. nud. *Geranium × intermedium* Sünd. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 220. 1912. TYPE LOCALITY: "Kulturhybride. – Von Sündermann in Lindau gezüchtet". TYPE: Germany. Cultivated in Lindau, *F. Sündermann s.n.* (no original material located).

### **G. argenteum × G. subcaulescens**

*Geranium × lindavicum* Sünd. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 220. 1912. TYPE LOCALITY: "Kulturhybride. – Von Sündermann in Lindau gezüchtet". TYPE: Germany. Cultivated in Lindau, *F. Sündermann s.n.* (no original material located).

### **G. asphodeloides × G. bohemicum**

*Geranium × decipiens* Hausskn., Mitth. Thüring. Bot. Vereins 5: 65. 1893. TYPE LOCALITY: "Hab. in derelictis pr. ruinas castelli turcici supra mon. Korona, parentibus consociatum". TYPE: Greece. Agrapha, monasterium Korona, 39°45'N, 21°30'E, 20-28 June 1885, *C. Haussknecht s.n.* (lectotype, here designated, JE image!). According to Hayek (1927: 571) this hybrid results from the cross *G. asphodeloides* and *G. lanuginosum*.

### **G. bohemicum × G. lanuginosum**

This hybrid was found by Dahlgren (1949) in a culture of *G. lanuginosum*, among seedlings from southern Sweden. Apparently it never has been formally de-

scribed. Previously it has been obtained by Dahlgren (1923) artificially. Bohlin (1997) indicated the first report of this hybrid in nature.

### **G. dahuricum × G. pratense**

*Geranium × bergianum* C.E. Lundstr., Acta Horti Berg. 5(3): 69, Taf. 3 Fig. 2. 1914. TYPE LOCALITY: [not indicated]. TYPE: probably cultivated at Bergius Botanic Garden, *C.E. Lundström s.n.* (no original material located).

### **G. dalmaticum × G. macrorrhizum**

*Geranium × cantabrigiense* Yeo, Hardy Geraniums: 153, 188, fig. 9.90C, pl. 34. 1985. TYPE LOCALITY: "Cult. Hort. Bot. Univ. Cantab., no. 232-74 Kiefer, sub nomine *G. dalmaticum × G. macrorrhizum* culta, 22. vi. 1983 lecta et in foliis herbarii tribus (holotypus et duo isotypi) conservatur (CGG)". TYPE: Cultivated. Botanical Garden Univ. Cambridge, 22 June 1983, *H. Wilder-Kiefer 232-74* (holotype, CGG).

### **G. endressii × G. traversii**

*Geranium × riversleaianum* Yeo, Hardy Geraniums: 67, 187, fig. 9.3, pl. 3. 1985. TYPE LOCALITY: "Cult. Hort. Bot. Univ. Cantab., no. 172-74 G.S. Thomas, sub nomine *Geranium 'Russell Prichard'*, 30. vii. 1975 lecta (CGG)". TYPE: Cultivated at Hort. Bot. Univ. Cantab., 30 July 1975, *G.S. Thomas 172-74* (holotype, CGG).

### **G. endressii × G. versicolor** [sometimes as *G. striatum*]

*Geranium × oxonianum* Yeo, Hardy Geraniums: 65, 187, fig. 9.2, pl. 2. 1985. TYPE LOCALITY: "Cult. Hort. Bot. Univ. Cantab., no. 24-74 G.S. Thomas, sub nomine *Geranium endressii × G. versicolor*: 'Claridge Druce', 30. vi. 1974 lecta et in foliis herbarii duobus conservatur (CGG)". TYPE: Cultivated at Cambridge Botanical Garden, 30 June 1974, *P. Yeo s.n.* (holotype, CGG).

Both species are allopatric, but hybrids of garden origin are widely cultivated (Van Loon 1984a: 167) and occasionally naturalized (McClintock 1975: 191). Marschall (1911: 551) indicated a spontaneous specimen of this hybrid growing in a garden.

### **G. ibericum × G. platypetalum**

*Geranium × magnificum* Hyl., Lustgården 42: 114, fig. 1. 1961. TYPE LOCALITY: "In hortis (saltem plerumque s.n. *G. platypetali*) pro ornamento colitur; a me in Anglia, Norvegia et Suecia visa.-Typus in UPS (H. Upsaliensis, sub divo cult., leg. I. Nordin 17. VI. 1960)". TYPE: Sweden. cultivated at Upsala Botanical Garden, 17 June 1960, *I. Nordin s.n.* (holotype, UPS color slide!).

*Geranium ibericum* var. *talyshense* E.F. Warb., New Phytol. 38: 144. 1938, nom. nud.

### **G. lividum [=G. phaeum] × G. phaeum**

*Geranium × phaeoides* Fritsch ex Jenčič, Oesterr. Bot. Z. 50: 43. 1900, nom. nud.

### **G. lucidum × G. robertianum**

*Geranium × hybridum* W. Allen ex C. Bailey in F. Lees, Bot. Loc. Rec. Club 3: 118. 1887, nom. illeg., non L., 1767. TYPE LOCALITY: "On old walls, 'Mill in Hole,' Bridgnorth, Salop; W. Allen". TYPE: Great Britain, Bridgnorth, 52°32'N, 2°25'W, *W. Allen s.n.* (no original material located). According to McClintock (1975: 192) it is known from a couple of localities from England, but no specimens has been traced.

### **G. molle × G. pyrenaicum**

*Geranium × luganense* Chenevard, Bull. Herb. Boissier ser. 2, 3: 427. 1903. TYPE LOCALITY: "Crocefisso, Mt S. Giorgio". TYPE: Switzerland. Tessin, Crocefisso, Mt S. Giorgio, 45°54'N, 8°57'E, *P. Chenevard s.n.* (no original material located). According to Van Loon (1984a: 167) this hybrid has been found only once in wild. *Geranium oenense*, sometimes considered an hybrid between *G. molle* and *G. pusillum* has been synonymized to *G. molle*.

### **G. phaeum [var. lividum] × G. reflexum**

*Geranium × monacense* nothovar. *anglicum* Yeo, Hardy Geraniums: 188. 1985. TYPE LOCALITY: "Cult. Hort. Bot. Univ. Cantab., no. 281-81 Forty, primo ex Hurst Green, east Sussex, a P. Roper lecta, exsicata sub nomine *G. phaeum* var. *lividum* 4. vi. 1982 lecta et in foliis herbarii duobus conservatur (CGG)". TYPE: Cultivated at Cambridge Botanical Garden, 4 June 1982, *P. Yeo s.n.* (holotype, CGG).

### **G. phaeum [var. phaeum] × G. reflexum**

*Geranium × monacense* Harz, Mitt. Bayer Bot. Ges. 4(1): 7. 1921. TYPE LOCALITY: "Wörthsee (Oberbayern)". TYPE: Germany, Oberbayern, Wörthsee, 48°05'N, 11°11'E, *K. Harz s.n.* (no original material located).

### **G. phaeum [var. lividum] × G. sylvaticum**

*Geranium × zermattense* Wolf ex Gams in Hegi, Ill. Fl. Mitt.-Eur. 4(3): 1715. 1924, nom. nud. Gams (1924: 1715) did not provided any description and indicated that this taxa was "very doubtful".

### **G. pratense × G. robertianum**

A hybrid between these species was reported by Drabble & Drabble (1908: 301) in England. According to McClin-

tock (1975: 190) no specimens has been traced, and the existence of such hybrid seems very unlikely.

#### **G. pusillum × G. pyrenaicum**

*Geranium hybridum* Hausskn., sometimes considered an hybrid between *G. pusillum* and *G. pyrenaicum*, has been here considered as synonym of *G. pusillum*.

#### **G. rivulare × G. sylvaticum**

*Geranium × besseanum* Gams in Hegi, Ill. Fl. Mitt.-Eur. 4(3): 1715. 1924, nom. nud. Gams (1924: 1715) did not provide any description to this taxa.

#### **G. sessiliflorum** [subsp. *novaezelandiae*] × **G. traversii** [var. *elegans*]

*Geranium × antipodeum* Yeo, Hardy Geraniums ed. 2: 211. 2002. TYPE LOCALITY: "cult. University Botanic garden, Cambridge, accession no. 1998.0471 Beckett, 2.xi.1979 (K) (from K. and G. Beckett...". TYPE: Cultivated at Cambridge Botanical Garden, 2 Nov. 1979, P. Yeo s.n. (holotype, K-000729507 image!).

## ACKNOWLEDGMENTS

Many individuals have helped in the elaboration and completion of this study, but I am especially grateful to Santiago Castroviejo (1946-2009), who provided support for this project both personally and professionally, and who, in many ways, made its completion possible. Sadly, he did not live to see the publication. I also owe a special thanks to M.J. Cano since without her insistence I would never have collected my articles on *Geranium* in a monograph and for her accurate criticism of each of its sections that she has reviewed with invaluable dedication and effort. My friends Carmen Navarro and Félix Muñoz Garmendia actively supported my work in its many aspects, as did Lourdes Rico, Kew Botanical Gardens, and Carmen Ulloa, Missouri Botanical Garden. I am indebted to the curators and staff of the herbaria mentioned in *Material and methods* for kindly providing specimens and other material for study. The collectors given special recognition because their effort for more than 200 years, often

in inhospitable or dangerous areas, has made this work possible. I also extend my appreciation to the journals, editors and anonymous reviewers of the previous papers on which this work is partly based for their critical reviews and for their helpful suggestions during the editing process. I would like to thank specially to the journals: *Annals of the Missouri Botanical Garden*, *Israel Journal of Botany*, *Systematic Botany*, and *Systematic Botany Monographs* for granting permission to use in this publication some of the plates previously published in these journals.

I wish to record my sincere thanks to Y. Abraham, G. Alessia, P.J. Alexander, M. Amadio, N. Askoy, C. Aupic, G. Aymard, G.G. Aymonin, G. Bailargeon, H. Balslev, M. Baltisberger, P. Barberá, G. Barboza, C. Bartram, C. Benedí, T. Block, K. Boardman, A. Bogaerts, D. Boufford, C. Brodie, R. Brummitt, P. Buek, A. Buira, P. Bures, V. Byalt, S. Cafferty, J. Calvo, E. Cameron, P. Catalán, D. Chabard, A. Charpin, F. Chiang, F. Conti, M.B. Crespo, S. D'Acunto, C.E. Darigo, P.N. Davies, J. de Lange, J. Delavie, A. Diamond, D. Dixon, A. Donatelli, R. Drinkwater, D. Dubovik, R. Duno, B. Martín, J. McNeill, L. Medina, R. Mill, P. Milne, A. Mora, R. Morales, P. Mráz, P. Muñoz-Rodríguez, J.G. Murrell, C. Nepi, S. Nishida, M. Novoselova, M. Niketić, P. Otto, J. Paiva, J. Pandalayil, F. Pando, Y.R. Paneru, J. Pedrol, P. Pelser, M. Peña, P. Perret, L. Perrie, V. Petronela, L. Pignotti, J. Pizarro, H.N. Qin, A. Quin-

tanar, R.K. Rabeler, L. Raenko, D. Ratunga, T. Ranker, P. Raven, G. Reid, A. Rhoads, E. Rico, R. Riina, Y. Roskov, Z. Rogers, T. Rouillard, C. Roux, J. Rukseniene, O. Ryding, M. Salas, A. Santangelo, F. Schmid, I. Schonberger, P. Schönfelder, F. Schuhwerk, M. Sequeira, A. Shimizu, D.-H. Son, M. Sosef, J. Stepanek, A. Stepanova, K. Sutorý, H. Takahashi, W. Takeuchi, M.T. Tellería, B. Tenbergen, G. Thijssse, M. Thulin, N. Turland, J. Valdés, M. Velayos, J. Veldkamp, D. Victor, E. Vitek, R. Vogt, H. Vonow, N. Walsh, J.J. van der Walt, Chiu-Mei Wang, S. Welsh, P. Yeo, T. Zanoni and Libing Zhang, for their helpful suggestions and very useful advice in many aspects.

P. Alexander, A. Buira, J. Calvo, A. Diamond, M.Á. García, A. Grau, J. Pedrol, A. Prunell, R. Riina, P. Sklenář, M. Sequeira and C. Ulloa have kindly allowed me to use their photographs of some species.

I am grateful to C. Aldana, P. Amorim, S. Beck, P. Cămara, A. Cano, M.J. Cano, L. Domínguez, A. Galán de Mera, M.T. Gallego, J.R. Grande, J. Guerra, L. Gutiérrez, J.A. Jiménez, S. Leiva, C. Marticorena, D. Minga, R. Rodríguez, N. Sanjines, G. Suárez, and M. Zapata for their kind assistance during field trips in Argentina, Bolivia, Brazil, Chile, Ecuador, Peru, and Venezuela, and also A. Bornia, A. Martín Ciudad, J.J. Quirós, J. Reyes and Y. Ruiz for their technical support. Xinying and Anne Martin kindly revised and corrected the English text.

Most of the drawings were made by J. Castillo and R. García Mora, plus some that were made by M. Cartañá, M. Chirino, E. Ortúñez and J. Pizarro.

This work was partly financed by the Spanish Government of the research projects (AMB1999-1290-E, REN2000-2093-E/GLO, PB91-0070-C03-00, PR2001-0342, REN2002-04634-C05-05, REN2003-00982/GLO, CGL2004-00172/BOS, CLG2007-60184/BOS, CGL2010-19747, CGL2011-28613-C03-01, CGL2014-52787-C3-1-P and CGL2017-85204-C3-1-P) and by the European Union through the COLPARSYST program.

## APPENDIX 1. CHROMOSOME COUNTS OF GERANIUM

Accepted names are in boldface. Between square brackets are indicated the names of the original publication if they differ from the accepted in this monograph. The country, locality, collector and herbarium that keeps the voucher are indicated when available (in parentheses). *Van Loon 3650, 11253, 11254, 11811, 12343* vouchers are attributed to different species and/or localities.

- Geranium aequale** [sub *G. molle* f. *preuschhoffii*]. Germany, Schleswig-Holstein, unknown collector (?):  $2n = 26$  (Gauger 1937: 529).
- G. aequale** [sub *G. molle* var. *aequale*]. Sweden, Skane, Lomma, Alnarp, Lövkist 1070 (LD):  $2n = 26$  (Lövkist & Hultgard 1999: 21).

- G. albanum**. unknown origin, unknown collector (?):  $n = 14$  (Warburg 1938a: 145).
- G. albanum**. unknown origin, cultivated material from several Botanical Gardens, *Van Loon 3452, 3504, 3507, 3533, 3534, 3535* (U):  $2n = 20$  (Van Loon 1984b: 276).
- G. albicans**. Argentina, Córdoba, entre La Serranita y Villa Ciudad de América, Barboza 9 (CORD?):  $n = 14$  (Barboza 1983: 143).
- G. albiflorum**. Russia, Buryatiya, Lake Baikal, Tarkulik, Belaeva & Siplivinsky 77-100 (LE):  $2n = 28$  (Belaeva & Siplivinsky 1981: 859).
- G. albiflorum**. Russia, Buryatiya, Istoki p. Šumilichi, unknown collector (?):  $2n = 28$  (Belaeva & Siplivinsky 1975: 869).
- G. albiflorum** [sub *G. albiflorum* var. *lilacinum*]. Russia, Irkutsk, unknown collector (?):  $2n = 28$  (Krogulevich 1978: 27).
- G. albiflorum** [sub *G. albiflorum* var. *lilacinum*]. Russia, Tunkinsky Alpes, East Sayan, unknown collector (?):  $2n = 26, 28$  (Krogulevich 1976: 49).
- G. arabicum** [sub *G. simense*]. Cameroon, Cameroons Mt, Morton & Venn K1271 (WAT, YA):  $2n = 28$  (Morton 1993: 168).
- G. arabicum** [sub *G. simense*]. Cameroon, Cameroons Mt, Morton K466 (WAT):  $2n = 28$  (Morton 1993: 168).
- G. arabicum**. Kenya, Mt Kenya, Hedberg 4136 (UPS):  $2n = 28$  (Hedberg & Hedberg 1977: 16).
- G. arabicum**. Kenya, Galama Mts, Hedberg 4136 (UPS):  $2n = 28$  (Hedberg & Hedberg 1977: 16).
- G. arabicum**. Tanzania, Kilimanjaro, Hedberg B 66159: 1 (UPS):  $2n = 28$  (Hedberg & Hedberg 1977: 16).
- G. arabicum**. Tanzania, Ngara distr., Kokwaro 1969 (?):  $2n = 28$  (Hedberg & Hedberg 1977: 16).
- G. arboreum**. USA, Hawaii, Maui, Puu Ni'aniau, Carr 906 (HAW):  $n = ca. 25$  (Carr 1978: 237).
- G. argenteum**. Italy, Verona, monte Baldo, Küpfer 3322 (NEU?):  $n = 14$  (Favarger & al. 1979: 52).
- G. argenteum**. Slovenia, Črna prst, unknown collector (LJU):  $2n = 28$  (Lovka & al. 1971: 790).
- G. argenteum**. unknown origin, cultivated at Kiel, Germany, unknown collector (?):  $2n = 28$  (Gauger 1937: 529).
- G. argenteum**. unknown origin, unknown collector (?):  $2n = 28$  (Warburg 1938a: 150).
- G. argenteum**. unknown origin, unknown collector (?):  $2n = 28$  (Warburg 1938a: 150).
- G. aristatum**. Bulgaria, Mt Vlahina, Petrova s.n. (SOM):  $2n = 26$  (Petrova 2006: 217).
- G. aristatum**. unknown origin, cultivated at München, Germany, unknown collector (?):  $2n = 28$  (Gauger 1937: 529).

- G. asphodeloides**. Bulgaria, Strandzha Mt, Petrova & Stanimirova 59200 (SOM):  $2n = 24$  (Petrova & Stanimirova 2003: 677).
- G. asphodeloides**. Greece, S of Kataphygion, Pieria Ori, 30 km E of Kozani, Baltisberger 11392 (ZT):  $2n = 24$  (Baltisberger 1991a: 165).
- G. asphodeloides**. Greece, Mt. Olympus, NW side, Petra to Kokkinoplos, Strid & al. G74-30-01 (C):  $2n = 30+f$  (Strid & Franzén 1981: 835).
- G. asphodeloides**. Greece, Thessalia, Kastania, Van Loon 24466 (U):  $2n = 24$  (Van Loon 1984b: 266).
- G. asphodeloides**. Greece, Mt Pindhos, Kastania, Van Loon 24466 (U):  $2n = 24$  (Van Loon & Oudemans 1982: 343).
- G. asphodeloides**. Turkey, Küçük Mesoraş, Kahraman 2185 (Middle East Technical University, Ankara):  $2n = 26$  (Martin & al. 2022: 8).
- G. asphodeloides**. unknown origin, unknown collector (?):  $n = 14, 2n = 28$  (Warburg 1938a: 145).
- G. ayavacense**. Peru, Cordillera de Vilcabamba, Terrier 7 02 24 (NEU):  $2n = 52$  (Huynh 1965: 67).
- G. berterioanum**. Chile, Región Metropolitana, Baños de Colina, Aedo 6737 (MA):  $2n = 56$  (Aedo & al. 2005a: 8).
- G. berterioanum**. Chile, Biobío, Concepción, Aedo 6913 (MA):  $2n = 84$  (Aedo & al. 2005a: 8).
- G. berterioanum**. Chile, Maule, Constitución, Aedo 7154 (MA):  $2n = 52$  (Aedo & al. 2005a: 8).
- G. berterioanum**. Chile, Magallanes, pr. Puerto Natales, Aedo 7459 (MA):  $2n = 84$  (Aedo & al. 2005a: 8).
- G. bicknellii**. Canada, Manitoba, Kings Park, Löve & Löve 5019 (COLO or WIN):  $2n = 52$  (Löve & Löve 1982: 348).
- G. bohemicum**. Bulgaria, summit Chivira, Petrova & Stanimirova 60200 (SOM):  $2n = 28$  (Petrova & Stanimirova 2003: 677).
- G. bohemicum**. Norway, Oslo, Dahlgren s.n. (?):  $2n = 28$  (Dahlgren 1952: 315).
- G. bohemicum**. Norway, Telemark, Nootdden, Hestasen, Van Loon 24184 (U):  $2n = 28$  (Van Loon 1984c: 294).
- G. bohemicum**. Sweden, Östergötland, Skedvi, Byle, Dahlgren s.n. (?):  $2n = 28$  (Dahlgren 1952: 315).
- G. bohemicum**. Sweden, Tyresö, Dahlgren s.n. (?):  $2n = 28$  (Dahlgren 1952: 315).
- G. bohemicum**. Sweden, Dalarna, Hedemora, Granby, Dahlgren s.n. (?):  $2n = 28$  (Dahlgren 1952: 315).
- G. bohemicum**. Sweden, Södermanland, Gryt, Rösunda, Dahlgren s.n. (?):  $2n = 28$  (Dahlgren 1952: 315).
- G. bohemicum**. Sweden, Medelpad, Timra, unknown collector (?):  $2n = 28$  (Dahlgren 1952: 315).

- G. bohemicum.** Sweden, Uppland, Blidö, *unknown collector* (?):  $2n = 28$  (Dahlgren 1952: 315).
- G. bohemicum.** Sweden, Tränke, Niesky, *Van Loon 15507* (U):  $2n = 28$  (Van Loon 1984c: 294).
- G. bohemicum.** Turkey, Bolu, between Bolu and Yedigöller, *Kahraman 2157* (Middle East Technical University, Ankara):  $2n = 28$  (Martin & al. 2022: 8).
- G. brevicaule** [sub *G. sessiliflorum* subsp. *novazelandiae*]. New Zealand, Archerfield, Waihao Forks, Canterbury, *Dawson & Beuzenberg s.n.* (CHR-517723):  $2n = 52$  (Dawson & Beuzenberg 2000: 5).
- G. brevicaule** [sub *G. sessiliflorum* var. *arenarium*]. New Zealand, Southland, Omaui, Three Sisters Dunes, *de Lange & al. s.n.* (AK-286142):  $n = 26$  (de Lange & al. 2004: 880).
- G. brevipes** [sub *G. ocellatum*]. Cameroon, Cameroons Mt, *Hedberg 3518A* (UPS):  $2n = 56$  (Hedberg & Hedberg 1977: 16).
- G. brevipes** [sub *G. ocellatum*]. Cameroon, Cameroons Mt, *Morton K584* (WAT):  $2n = 56$  (Morton 1993: 168).
- G. brevipes** [sub *G. ocellatum*]. Cameroon, Cameroons Mt, *Morton K728* (WAT, K, S):  $2n = 56$  (Morton 1993: 168).
- G. caeruleatum.** Bulgaria, Pirin Mt, Bajuví dupki, Kamenitica, *Andreev NA-8042* (SOM):  $2n = 28$  (Andreev 1982: 576).
- G. caeruleatum.** Bulgaria, Vitosha Mt, *Petrova 7200* (SOM):  $2n = 28, 56$  (Petrova & Stanimirova 2002: 454).
- G. caespitosum.** USA, New Mexico, Doña Ana Co., Organ Mtns., Aguirre Springs Recreation Area, *Arsuffi 81-157* (NMC):  $n = 26$  (Ward 1984: 58).
- G. cafferum.** South Africa, Somerset East, Buffelshoekse pass, on R337 N from Pearson, *Gibby & Barret 462* (BM):  $2n = 22$  (unpublished).
- G. carolinianum** [sub *G. sphaerospermum*]. Canada, Ontario, Abitibi co., Iroquois Falls, *Bassett & Baldwin 4015* (DAO):  $2n = 52$  (Löve 1965: 195).
- G. carolinianum.** Canada, Manitoba, St. Elizabeth, Löve & Löve 5890 (COLO or WIN):  $2n = 52$  (Löve & Löve 1982: 348).
- G. carolinianum.** unknown origin, *unknown collector* (?):  $2n = 46-48$  (Warburg 1938a: 142).
- G. carolinianum.** USA, Idaho, Idaho Co., *Davis 2290* (UTC):  $2n = 52$  (Shaw 1952: 299).
- G. cataractarum** [sub *G. cataractarum* subsp. *pitardii*]. Morocco, Moyen Atlas, entre Aïn Leuh et Oum Er Bia, *Guittonneau 72.07.08.01* (herb. Guittonneau):  $2n = 36$  (Guittonneau 1975: 200).
- G. cataractarum** [sub *G. cataractarum* subsp. *pitardii*]. Morocco, Moyen Atlas, falaise de Senoual, pr. Bekrit, *Guittonneau 72.07.10.05* (herb. Guittonneau):  $2n = 36$  (Guittonneau 1975: 200).
- G. cataractarum.** Spain, Sierra de Cazorla, Jaén (plants sent to Kew, received at Cambridge and raised at Greenport, Long Island, New York), *Barneby 240-70* (CGG):  $2n = 36$  (Yeo 1973a: 345).
- G. cataractarum.** Spain, Jaén, Orcera, barranco del río Madera, Calar de Peña Rubia, *Pajarón 1266* (MA):  $2n = 36$  (Pajarón 1983: 273).
- G. cataractarum.** Spain, Jaén, sierra de Cazorla, *Van Loon 12614* (U):  $2n = 36$  (Van Loon 1984b: 266).
- G. cazorlense.** Spain, Jaén, Sierra del Pozo, Cerro Cabañas, *Küpfer K01431* (NEU):  $2n = 28$  (Küpfer 1974: 34).
- G. cinereum.** France, Vallée d'Ossoue, Petit Pic de Tapou, *Küpfer K01433* (NEU):  $2n = 28$  (Küpfer 1974: 34).
- G. cinereum.** Spain, Navarra, Pic d'Orhy, crête SW, *Küpfer K01434* (NEU):  $2n = 28$  (Küpfer 1974: 34).
- G. cinereum.** Spain, Huesca, Parque Nacional de Ordesa, Soaso, *Van Loon 15495* (U):  $2n = 28$  (Van Loon 1984b: 266).
- G. cinereum.** unknown origin, cultivated at München, Germany, *unknown collector* (?):  $2n = 28$  (Gauger 1937: 529).
- G. cinereum.** unknown origin, *unknown collector* (?):  $n = 14$  (Warburg 1938a: 150).
- G. collinum.** Russia, *Van Loon 22399* (U):  $2n = 28$  (Van Loon 1984b: 266).
- G. collinum.** Turkey, Ardahan, Haçuvan village, *Kahraman 2170* (Middle East Technical University, Ankara):  $2n = 28$  (Martin & al. 2022: 8).
- G. collinum** [sub *G. collinum* var. *glandulosum*]. unknown origin, *unknown collector* (?):  $2n = 28$  (Warburg 1938a: 144).
- G. columbinum.** Scandinavia, *unknown collector* (?):  $2n = 18$  (Löve & Löve 1945: 17).
- G. columbinum.** Albania, Durrës, *Strid 0509* (LD):  $2n = 18$  (Strid 1971: 492).
- G. columbinum.** Bosnia-Herzegovina, vic. Turbe, *Van Loon 17276* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** Bosnia-Herzegovina, vic. Dobrun, *Van Loon 17361* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** Bulgaria, Stara Planina, vic. Sliven, *Van Loon 25288* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** Bulgaria, Black Sea coast, around Aladzha monastir, *Petrova 23242* (SOM):  $2n = 18$  (Petrova & Stanimirova 2001: 460).
- G. columbinum.** Croatia, Istria, Zminj, *Van Loon 17189* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** Croatia, Istria, Rovinj, *Van Loon 3647* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** Czech Republic, vic. Liberec, *Van Loon 18917* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Var, Presqu'île-de-Giens, *Van Loon 10133* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Yonne, Vézelay, *Van Loon 11248* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Saône-et-Loire, Velay, *Van Loon 11250* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Pyrénées-Orientales, Thuès entre Vals, *Van Loon 11818* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Saône-et-Loire, Givry, *Van Loon 18913* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, *Van Loon 3477* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Côte-d'Or, Chaux-Urcy, *Van Loon 3637* (U):  $2n = 18$  (Van Loon 1984c: 294).
- G. columbinum.** France, Hérault, Hérault, St. Étienne d'Issenac, *Van Loon 5974* (U):  $2n = 18$  (Van Loon 1984c: 294).

*Geranium angulosum* Mill., *Gard. Dict.* ed. 8 n.º 22. 1768, [*Pelargonium*].

*Geranium angustifolium* L'Hér. ex R. Knuth in *Engl., Pflanzenr.* IV.129 (Heft 53): 420. 1912, [*Pelargonium*], nom. nud.

*Geranium angustifolium* Thunb., *Prodr. Fl. Cap.*: 113. 1800, [*Pelargonium*].

*Geranium anthemifolium* (M. Bieb.) Poir. in *Lam., Encycl. Suppl.* 2: 742. 1812, [*Erodium*].

*Geranium aphanoides* Thunb., *Prodr. Pl. Cap.*: 113. 1800, [*Pelargonium*].

*Geranium apiifolium* Andrews, *Geraniums* 2, [pl. 3]. 1805, [*Pelargonium*].

*Geranium appendiculatum* L. f., *Suppl. Pl.*: 304. 1782, [*Pelargonium*].

*Geranium arborescens* Desf., *Fl. Atlant.* 2: 110. 1798, [*Erodium*].

*Geranium ardens* Andrews, *Geraniums* 1, [pl. 28]. 1805, [*Pelargonium*].

*Geranium ardens* var. *ardescens* Andrews, *Geraniums* 2, [pl. 4]. 1805, [*Pelargonium*].

*Geranium ardens* var. *minor* Andrews, *Geraniums* 1, [pl. 29]. 1805, [*Pelargonium*].

*Geranium ardescens* Andrews, *Geraniums* 1. 1805, [*Pelargonium*].

*Geranium arduinum* L., *Sp. Pl.* ed. 2: 952. 1763, [*Erodium*].

*Geranium arenarium* Burm. f., *Spec. Bot. Geran.*: 48. 1759, [*Erodium*].

*Geranium arenicola* Steud., *Flora* 39(28): 439. 1856, [*Erodium*].

*Geranium articulatum* Cav., *Diss.* 4: 252, tab. 122 fig. 1. 1787, [*Pelargonium*].

*Geranium asperifolium* Andrews, *Geraniums* 1, [pl. 2]. 1805, [*Pelargonium*].

*Geranium asperum* (Willd.) Poir. in *Lam., Encycl. Suppl.* 2: 759. 1812, [*Pelargonium*].

*Geranium asplenioides* Desf., *Fl. Atlant.* 2: 109, tab. 168. 1798, [*Erodium*].

*Geranium astragalifolium* Andrews, *Bot. Repos.* 3, pl. 190. 1801, [*Pelargonium*].

*Geranium astragalifolium* Cav., *Diss.* 3: [186]. 1787, [*Pelargonium*], nom. nud.

*Geranium astragalifolium* Cav., *Diss.* 4: 257, tab. 104 fig. 2. 1787, [*Pelargonium*].

*Geranium astragalifolium* var. *ardens* Andrews, *Geraniums* 2, [pl. 7]. 1805, [*Pelargonium*].

*Geranium astragalifolium* var. *multifidum* Andrews, *Geraniums* 2, [pl. 7]. 1805, [*Pelargonium*].

*Geranium atro-fulgens* Andrews, *Geraniums* 2, [pl. 8]. 1805, [*Pelargonium*].

## APPENDIX 2. NAMES OF GERANIUM BELONGING TO OTHER GENERA

The names described or combined under *Geranium* and now transferred to other genera (indicated between square brackets) are listed here, because of their interest to the nomenclature of the genus *Geranium*. Nevertheless, their status should be investigated further, particularly those with the same epithet. A part of these names with the same epithet are probably “isonyms”, that is names based on the same type that have been published independently at different times, by different authors (art. 6.3, note 2). Consequently, the later isonyms should be disregarded. Another part becomes homonyms and

- Geranium atrum* (L'Hér.) Poir. in Lam., Encycl. Suppl. 2: 746. 1812, [Pelargonium].
- Geranium augustum* Andrews, Geraniums 1, [pl. 3]. 1805, [Pelargonium].
- Geranium auriculatum* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 745. 1812, [Pelargonium].
- Geranium auritum* L., Sp. Pl.: 679. 1753, [Pelargonium].
- Geranium australe* (Willd.) Dum. Cours., Bot. Cult. 5: 381. 1805, [Pelargonium].
- Geranium balsameum* (Jacq.) Dum. Cours., Bot. Cult. ed. 2, 5: 27. 1811, [Pelargonium].
- Geranium barbatum* (Jacq.) Andrews, Bot. Repos. 5, pl. 303. 1803, [Pelargonium].
- Geranium barbatum* var. *minor* Andrews, Bot. Repos. 5, pl. 323. 1803, [Pelargonium].
- Geranium barbatum* var. *undulatum* Andrews, Bot. Repos. 6, pl. 366. 1804, [Pelargonium].
- Geranium barringtonii* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 751. 1812, [Pelargonium].
- Geranium beaufortiae* Andrews, Geraniums 1, [pl. 4]. 1805, [Pelargonium].
- Geranium beaufortianum* (Desf.) Dum. Cours., Bot. Cult. ed. 2, 5: 25. 1811, [Pelargonium].
- Geranium beaufortianum* (Desf.) Poir. in Lam., Encycl. Suppl. 2: 748. 1812, [Pelargonium].
- Geranium beaufortianum* Desf. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 505. 1912, [Pelargonium], nom. nud., pro syn.
- Geranium betonicum* Burm. f., Spec. Bot. Geran.: 32. 1759, [Pelargonium].
- Geranium betulinum* L., Sp. Pl.: 679. 1753, [Pelargonium].
- Geranium bicolor* Jacq., Hort. Bot. Vindob. 3: 23, tab. 39. 1776, [Pelargonium].
- Geranium bicolor* var. *magna* Andrews, Geraniums 2, [pl. 9]. 1805, [Pelargonium].
- Geranium biflorum* Burm. ex Cav., Diss. 4: 251. 1787, [Pelargonium].
- Geranium bifolium* Burm. f., Spec. Bot. Geran.: 52. 1759, [Pelargonium].
- Geranium bipinnatum* Cav., Diss. 5: 273, tab. 126 fig. 3. 1788, [Erodium].
- Geranium blandfordium* Andrews, Geraniums 2, [pl. 10]. 1805, [Pelargonium].
- Geranium blattarium* (Jacq.) Poir. in Lam., Encycl. Suppl. 2: 748. 1812, [Pelargonium].
- Geranium botrys* Cav., Diss. 4: 218, tab. 90 fig. 2. 1787, [Erodium].
- Geranium broadleyae* Andrews, Geraniums 1, [pl. 7]. 1805, [Pelargonium].
- Geranium bubonifolium* Andrews, Bot. Repos. 5, pl. 328. 1803, [Pelargonium].
- Geranium canariense* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 752. 1812, [Pelargonium].
- Geranium capillare* Cav., Diss. 4: 258, tab. 97 fig. 1. 1787, [Pelargonium].
- Geranium capillare* Cav., Diss. 3: [186]. 1787, [Pelargonium], nom. nud.
- Geranium capitatum* L., Sp. Pl.: 678. 1753, [Pelargonium].
- Geranium carneum* (Jacq.) Dum. Cours., Bot. Cult. ed. 2, 5: 7. 1811, [Pelargonium].
- Geranium carnosum* L., Cent. Pl. I: 20. 1755, [Pelargonium].
- Geranium caucalifolium* (Jacq.) Poir. in Lam., Encycl. Suppl. 2: 750. 1812, [Pelargonium].
- Geranium ceratophyllum* (L'Hér.) Dum. Cours., Bot. Cult. 3: 27. 1802, [Pelargonium].
- Geranium chaerophyllum* Cav., Diss. 4: 226, tab. 95 fig. 1. 1787, [Erodium].
- Geranium chamaedrifolium* (Jacq.) Poir. in Lam., Encycl. Suppl. 2: 747. 1812, [Pelargonium].
- Geranium chamaedryoides* Cav., Diss. 3: [186]. 1787, [Erodium], nom. nud.
- Geranium chamaedryoides* Cav., Diss. 4: 197, tab. 76 fig. 2. 1787, [Erodium].
- Geranium chelidonium* Houtt., Nat. Hist. 10: 8, pl. 61 fig. 1. 1779, [Pelargonium].
- Geranium chium* Burm. f., Spec. Bot. Geran.: 32. 1759, [Erodium].
- Geranium cicionium* L., Cent. Pl. I: 21. 1755, [Erodium].
- Geranium cicutarium* Cav. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 279. 1912, [Erodium], nom. nud., pro syn.
- Geranium cicutarium* L., Sp. Pl.: 680. 1753, [Erodium].
- Geranium cicutarium* var. *album* Weston, Bot. Univ. 2: 349. 1771, [Erodium].
- Geranium cicutarium* var. *chaerophyllum* (Cav.) Gaudin, Fl. Helv. 4: 395. 1829, [Erodium].
- Geranium cicutarium* var. *erectum* Weston, Bot. Univ. 2: 349. 1771, [Erodium].
- Geranium cicutarium* var. *moschatum* L., Sp. Pl.: 680. 1753, [Erodium].
- Geranium cicutarium* var. *pilosissimum* Gaudin, Fl. Helv. 4: 396. 1829, [Erodium].
- Geranium cicutarium* var. *pimpinellifolium* (Cav.) Gaudin, Fl. Helv. 4: 394. 1829, [Erodium].
- Geranium ciliatum* Andrews, Bot. Repos. 4, pl. 247. 1802, [Pelargonium].
- Geranium ciliatum* Cav., Diss. 4: 234, tab. 118 fig. 2. 1787, [Pelargonium].
- Geranium ciliatum* Thunb., Prodr. Pl. Cap.: 113. 1800, [Pelargonium].
- Geranium citriodorum* Andrews, Geraniums 1, [pl. 14]. 1805, [Pelargonium].
- Geranium citriodorum* Cav., Icon. 1: 6, tab. 8. 1791, [Pelargonium].
- Geranium concavifolium* (Pers.) Dum. Cours., Bot. Cult. ed. 2, 5: 46. 1811, [Pelargonium].
- Geranium condensatum* (Pers.) Poir. in Lam., Encycl. Suppl. 2: 757. 1812, [Pelargonium].
- Geranium conduplicatum* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 751. 1812, [Pelargonium].
- Geranium consanguineum* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 759. 1812, [Pelargonium].
- Geranium cordifolium* Andrews, Geraniums 1, [pl. 20]. 1805, [Pelargonium].
- Geranium cordifolium* Cav., Diss. 4: 240, tab. 117 fig. 3. 1787, [Pelargonium].
- Geranium cordifolium* Cav., Diss. 3: [186]. 1787, [Pelargonium], nom. nud.
- Geranium cordifolium* var. *squarrosus* Dum. Cours., Bot. Cult. 3: 17. 1802, [Pelargonium].
- Geranium coriandrifolium* L., Sp. Pl. ed. 2: 949. 1763, [Pelargonium].
- Geranium coronillaefolium* Andrews, Bot. Repos. 5, pl. 305. 1803, [Pelargonium].
- Geranium coronopifolium* Andrews, Bot. Repos. 5, pl. 338. 1803, [Pelargonium].
- Geranium corsicum* (DC.) Poir. in Lam., Encycl. Suppl. 2: 743. 1812, [Erodium].
- Geranium cortusaefolium* Andrews, Bot. Repos. 2, pl. 121. 1800, [Pelargonium].
- Geranium cortusaeefolium* var. *cortusoides* Andrews, Geraniums 2, [pl. 10]. 1805, [Pelargonium].
- Geranium cotyledonis* L., Mant. Pl. Altera: 569. 1771, [Pelargonium].
- Geranium crassicaule* (L'Hér.) Dum. Cours., Bot. Cult. 3: 18. 1802, [Pelargonium].
- Geranium crassicaule* (L'Hér.) Dum. Cours. ex Andrews, Geraniums 2, [pl. 13]. 1805, [Pelargonium].
- Geranium crassicaule* (L'Hér.) Poir. in Lam., Encycl. Suppl. 2: 752. 1812, [Pelargonium].
- Geranium crassifolium* Cav., Diss. 4: 219, tab. 90 fig. 1. 1787, [Erodium].
- Geranium crassifolium* Desf., Fl. Atlant. 2: 111. 1798, [Erodium].
- Geranium crassifolium* Forssk., Fl. Aegypt.-Arab.: 123. 1775, [Erodium].
- Geranium crassifolium* L'Hér. in Aiton, Hort. Kew.: 414. 1789, [Erodium].
- Geranium crassum* Poir. in Lam., Encycl. Suppl. 2: 741. 1812, [Erodium].
- Geranium crataegifolium* Roth, Bot. Abh. Beobacht.: 50, tab. 9. 1787, [Pelargonium].
- Geranium crataegifolium* Thunb., Prodr. Pl. Cap.: 115. 1800, [Pelargonium].
- Geranium crenatum* Andrews, Geraniums 2, [pl. 14]. 1805, [Pelargonium].
- Geranium crenatum* var. *mollifoliata* Andrews, Geraniums 2, [pl. 15]. 1805, [Pelargonium].
- Geranium crenatum* var. *monstrosiflorum* Andrews, Geraniums 2, [pl. 16]. 1805, [Pelargonium].
- Geranium crispum* L. ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 257. 1912, [Pelargonium], nom. nud., pro syn.
- Geranium crispum* P.J. Bergius, Descr. Pl. Cap.: 176. 1767, [Pelargonium].
- Geranium crithmifolium* (Sm.) Poir. in Lam., Encycl. Suppl. 2: 756. 1812, [Pelargonium].
- Geranium cucullatum* L., Sp. Pl.: 677. 1753, [Pelargonium].
- Geranium cucullatum* var. *barringtoniae* (Willd.) Dum. Cours., Bot. Cult. 5: 370. 1805, [Pelargonium].

*Geranium cucullatum* var. *fimbriatum* Burm. f., Spec. Bot. Geran.: 35. 1759, [*Pelargonium*].  
*Geranium cucullatum* var. *lobatum* Dum. Cours., Bot. Cult. ed. 2, 5: 20. 1811, [*Pelargonium*].  
*Geranium cuspidatum* Andrews, Geraniums 2, [pl. 55]. 1805, [*Pelargonium*].  
*Geranium cynosbatifolium* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 758. 1812, [*Pelargonium*].  
*Geranium daucifolium* Murray, Commentat. Soc. Regiae Sci. Gott. 3: 13, tab. 4. 1780, [*Pelargonium*].  
*Geranium daucifolium* Thunb., Prodr. Pl. Cap.: 116. 1800, [*Pelargonium*].  
*Geranium decumbens* Balb., Cat. Pl. ed. 1814: 11. 1814, [*Pelargonium*].  
*Geranium delphinifolium* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 752. 1812, [*Pelargonium*].  
*Geranium dentatum* Andrews, Geraniums 1, [pl. 22]. 1805, [*Pelargonium*].  
*Geranium dentatum* var. *album* Andrews, Geraniums 1, [pl. 25]. 1805, [*Pelargonium*].  
*Geranium denticulatum* (Jacq.) Dum. Cours., Bot. Cult. ed. 2, 5: 2. 1811, [*Pelargonium*].  
*Geranium dianthiflorum* Andrews, Geraniums 2, [pl. 17]. 1805, [*Pelargonium*].  
*Geranium dipetalum* (L'Hér.) Poir. in Lam., Encycl. Suppl. 2: 744. 1812, [*Pelargonium*].  
*Geranium diphyllosum* L'Hér. ex DC., Prodr. 1: 646. 1824, [*Erodium*], nom. nud., pro syn.  
*Geranium divaricatum* Thunb., Prodr. Fl. Cap.: 115. 1800, [*Pelargonium*].  
*Geranium diversifolium* (J.C. Wendl. ex Willd.) Poir. in Lam., Encycl. Suppl. 2: 750. 1812, [*Pelargonium*].  
*Geranium echinatum* Thunb., Prodr. Fl. Cap.: 114. 1800, [*Pelargonium*].  
*Geranium echinatum* var. *rubro-purpureo* Andrews, Bot. Repos. 3, pl. 158. 1801, [*Pelargonium*].  
*Geranium echinatum* var. *saepeflorens* Andrews, Geraniums 1, [pl. 54]. 1805, [*Pelargonium*].  
*Geranium elegans* Andrews, Bot. Repos. 1, pl. 28. 1798, [*Pelargonium*].  
*Geranium elegans* Dum. Cours., Bot. Cult. ed. 2, 5: 9. 1811, [*Pelargonium*].  
*Geranium ellipticum* Thunb., Fl. Cap. ed. 2: 525. 1823, [*Pelargonium*].  
*Geranium elongatum* Cav., Diss. 3: [186]. 1787, [*Pelargonium*], nom. nud.  
*Geranium elongatum* Cav., Diss. 4: 233, tab. 101 fig. 3. 1787, [*Pelargonium*].  
*Geranium emarginatum* L. f., Suppl. Pl.: 306. 1782, [*Monsonia*].  
*Geranium emarginatum* Thunb., Prodr. Pl. Cap.: 112. 1800, [*Monsonia*].  
*Geranium ensatum* Thunb., Prodr. Fl. Cap.: 113. 1800, [*Pelargonium*].  
*Geranium eriostemon* (Jacq.) Poir. in Lam., Encycl. Suppl. 2: 759. 1812, [*Pelargonium*].

*Geranium erodiiflorum* Souza Brito, Rev. Fl. Med. 4: 571. 1938, [*Pelargonium*], nom. inval., without Latin description (art. 39.1)  
*Geranium erodium* L'Hér. ex Dum. Cours., Bot. Cult. 3: 28. 1802, [*Pelargonium*], nom. nud., pro syn.  
*Geranium eximium* Andrews, Geraniums 1, [pl. 37]. 1805, [*Pelargonium*], nom. nud.  
*Geranium expansum* Thunb., Prodr. Pl. Cap.: 112. 1800, [*Pelargonium*].  
*Geranium exstipulatum* Cav., Diss. 4: 253, tab. 123 fig. 1. 1787, [*Pelargonium*].  
*Geranium ferulaceum* Burm. f., Spec. Bot. Geran.: 52. 1759, [*Pelargonium*].  
*Geranium ficaria* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 745. 1812, [*Pelargonium*].  
*Geranium fissifolium* Andrews, Bot. Repos. 6, pl. 378. 1804, [*Pelargonium*].  
*Geranium fissilium* Andrews ex Dum. Cours., Bot. Cult. ed. 2, 5: 47. 1811, [*Pelargonium*], ortho. var.  
*Geranium flabellatum* Desf. ex Dum. Cours., Bot. Cult. ed. 2, 5: 35. 1811, [*Pelargonium*], nom. nud.  
*Geranium flavum* Burm. f., Fl. Indica: 19. 1768, [*Pelargonium*].  
*Geranium flavum* L., Mant. Pl.: 257. 1767, [*Pelargonium*].  
*Geranium flexuosum* Thunb., Prodr. Pl. Cap.: 116. 1800, [*Pelargonium*].  
*Geranium floribundum* Andrews, Bot. Repos. 6, pl. 420. 1805, [*Pelargonium*].  
*Geranium foetidum* L., Fl. Monsp.: 21. 1756, [*Erodium*], nom. nud.  
*Geranium foetidum* L., Amoen. Acad. 4: 487. 1759, [*Erodium*].  
*Geranium foetidum* L. ex B.D. Jacks., Proc. Linn. Soc. London Suppl. 1912: 79. 1912, [*Erodium*], nom. inval., not accepted by its author (art. 36.1)  
*Geranium foliaceum* Andrews, Geraniums 2, [pl. 29]. 1805, [*Pelargonium*], nom. nud.  
*Geranium formosum* (Desf.) Poir. in Lam., Encycl. Suppl. 2: 748. 1812, [*Pelargonium*].  
*Geranium formosum* Andrews, Geraniums 2, [pl. 18]. 1805, [*Pelargonium*].  
*Geranium formosum* Dum. Cours., Bot. Cult. 5: 380. 1805, [*Pelargonium*].  
*Geranium formosum* var. *maculatum* Andrews, Geraniums 2, [pl. 19]. 1805, [*Pelargonium*].  
*Geranium fothergillianum* Andrews ex R. Knuth in Engl., Pflanzenr. IV.129 (Heft 53): 513. 1912, [*Pelargonium*], nom. nud., pro syn.  
*Geranium fothergillum* Andrews, Geraniums 2, [pl. 20]. 1805, [*Pelargonium*].  
*Geranium fragile* (Willd.) Dum. Cours., Bot. Cult. 5: 383. 1805, [*Pelargonium*].  
*Geranium fragile* Andrews, Bot. Repos. 1, pl. 37. 1798, [*Pelargonium*].  
*Geranium fragrans* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 751. 1812, [*Pelargonium*].  
*Geranium fragrans* Dum. Cours., Bot. Cult. 3: 22. 1802, [*Pelargonium*].

*Geranium fruticosum* Cav., Diss. 4: 263, tab. 122 fig. 2. 1787, [*Pelargonium*].  
*Geranium fulgidum* L., Sp. Pl.: 676. 1753, [*Pelargonium*].  
*Geranium fuscatum* (Jacq.) Dum. Cours., Bot. Cult. ed. 2, 5: 22. 1811, [*Pelargonium*].  
*Geranium geifolium* Desf., Fl. Atlant. 2: 108. 1798, [*Erodium*].  
*Geranium gibbosum* L., Sp. Pl.: 677. 1753, [*Pelargonium*].  
*Geranium glabrum* Dum. Cours., Bot. Cult. 3: 27. 1802, [*Pelargonium*].  
*Geranium glandulosum* Cav. in Lam., Encycl. 2: 665. 1788, [*Erodium*].  
*Geranium glaucoides* Andrews, Geraniums 1, [pl. 35]. 1805, [*Pelargonium*].  
*Geranium glaucophyllum* L., Sp. Pl.: 679. 1753, [*Erodium*].  
*Geranium glaucum* Andrews, Geraniums 1, [pl. 34]. 1805, [*Pelargonium*].  
*Geranium glaucum* Burm. f., Spec. Bot. Geran.: 47, tab. 1 n. 62. 1759, [*Pelargonium*].  
*Geranium glaucum* Cav., Diss. 4: 237, tab. 103 fig. 2. 1787, [*Pelargonium*].  
*Geranium glaucum* L. f., Suppl. Pl.: 306. 1782, [*Pelargonium*].  
*Geranium glomeratum* Andrews, Geraniums 2, [pl. 24]. 1805, [*Pelargonium*].  
*Geranium glutinosum* Jacq., Icon. Pl. Rar. 1: 13, tab. 131. 1783?, [*Pelargonium*].  
*Geranium glutinosum* L'Hér. ex Dum. Cours., Bot. Cult. 3: 21. 1802, [*Pelargonium*].  
*Geranium grandiflorum* Andrews, Bot. Repos. 1, pl. 12. 1798, [*Pelargonium*].  
*Geranium grandiflorum* Cav. ex B. D. Jacks., Index Kew. 2: 1019. 1893, [*Grieliem*], nom. inval., not accepted by its author (art. 36.1).  
*Geranium grandiflorum* L., Sp. Pl.: 683. 1753, [*Grieliem grandiflorum* (L.) Druce; Neuradaceae].  
*Geranium grandiflorum* var. *formania* Andrews, Geraniums 1, [pl. 33]. 1805, [*Pelargonium*].  
*Geranium grandiflorum* var. *parvifoliata* Andrews, Geraniums 1, [pl. 32]. 1805, [*Pelargonium*].  
*Geranium gratum* (Willd.) Poir. in Lam., Encycl. Suppl. 2: 758. 1812, [*Pelargonium*].  
*Geranium graveolens* Thunb., Prodr. Fl. Cap.: 115. 1800, [*Pelargonium*].  
*Geranium grenvilliae* Andrews, Geraniums 1, [pl. 63]. 1805, [*Pelargonium*].  
*Geranium grossularioides* L., Sp. Pl.: 679. 1753, [*Pelargonium*].  
*Geranium gruinum* L., Sp. Pl.: 680. 1753, [*Erodium*].

## INDEX TO SCIENTIFIC NAMES

*Geraniopsis* Chrtek, 714  
*trilophum* (Boiss.) Chrtek, 714  
*yemense* (Deflers) Chrtek, 716  
**Geranium** L., 41  
 [§] *Batrachia* Boiss., 786  
 [§] *Robertiana* Boiss., 744  
 [§] *Subacaulia* Boiss., 76  
 [§] *Tuberosa* Boiss., 649  
 [§] *Unguiculata* Boiss., 779  
 [trib.] *Columbina* Fr., 786  
 [trib.] *Sylvatica* Fr., 786  
 sect. **Aculeolata** Yeo, 73  
 sect. *Alternifolia* Paol., 66  
 sect. *Andina* R. Knuth, 111  
 sect. *Anemonifolia* R. Knuth, 744  
 sect. *Australiensia* R. Knuth, 111

sect. *Azorelloida* Aedo, 111  
 sect. *Batrachia* L., 786  
 sect. *Batrachia* W.D.J. Koch, 786  
 sect. **Batrachioidea** W.D.J. Koch, 692  
 sect. *Biflora* R. Knuth, 111  
 sect. *Bohemica* Tzvelev, 668  
 sect. **Brasilensia** R. Knuth, 105  
 sect. *Caespitosa* R. Knuth, 111  
 sect. *Chilensis* R. Knuth, 111  
 sect. *Columbina* W.D.J. Koch, 110  
 sect. *Dahurica* Tsyren., 111  
 sect. *Diffusa* R. Knuth, 111  
 sect. **Dissecta** Yeo, 638  
 sect. **Divaricata** Rouy, 708  
 sect. *Eriantha* Novoselova, 111  
 sect. **Erodioidea** Picard, 66  
 sect. *Eugeranium* Godr., 786  
 sect. *Fruticulosa* R. Knuth, 111  
 sect. **Geranium**, 110  
 sect. *Geranotypus* Dumort., 786  
 sect. *Gracilia* R. Knuth, 111  
 sect. *Hederacea* Paol., 111  
 sect. **Incana** Reiche, 587  
 sect. *Incanoidea* R. Knuth, 111  
 sect. **Lauginosa** Rouy, 668  
 sect. *Laxicaulia* R. Knuth, 111  
 sect. *Lucida* R. Knuth, 744  
 sect. *Mexicana* R. Knuth, 111  
 sect. *Neoandina* Aedo, 111  
 sect. **Neurophyllodes** A. Gray, 572  
 sect. *Orientalia* (Tsyren.) Novoselova, 111  
 sect. *Palustria* R. Knuth, 111  
 sect. **Paramensia** R. Knuth, 568  
 sect. *Perennia* Boiss., 786  
 sect. *Petraea* Bubani, 76  
 sect. *Petraea* R. Knuth, 111  
 sect. **Polyantha** Reiche, 730  
 sect. *Pyrenaica* R. Knuth, 692  
 sect. *Recurvata* (R. Knuth) Novoselova, 111  
 sect. *Reflexa* R. Knuth, 66  
 sect. *Renifolia* R. Knuth, 111  
 sect. *Robertiana* Boiss. ex Reiche, 744  
 sect. *Robertium* (Picard) Godr., 744  
 sect. **Ruberta** Dumort., 744  
 sect. *Rupicola* R. Knuth, 111  
 sect. *Sanguinea* R. Knuth, 111  
 sect. *Sibirica* R. Knuth, 111  
 sect. *Simensia* R. Knuth, 111  
 sect. *Sobolifera* Novoselova, 111  
 sect. *Striata* R. Knuth, 111  
 sect. *Strigosa* C.C. Huang & L.R. Xu, 730  
 sect. **Subacaulia** (Boiss.) Reiche, 76  
 sect. *Sylvatica* Bubani, 786  
 sect. **Trilopha** Yeo, 714  
 sect. *Trygonium* Dumort., 110  
 sect. **Tuberosa** (Boiss.) Reiche, 649  
 sect. **Unguiculata** (Boiss.) Reiche, 779  
 series *Ambigua* H.E. Moore, 786  
 series *Atropurpurea* H.E. Moore, 786  
 series *Bella* H.E. Moore, 786  
 series *Campanulatae* Paray, 786  
 series *Caroliniana* H.E. Moore, 786  
 series *Crenata* H.E. Moore, 786  
 series *Deltoidea* H.E. Moore, 786  
 series *Lata* H.E. Moore, 786

series *Nivea* H.E. Moore, 786  
 series *Repentia* H.E. Moore, 786  
 series *Resima* H.E. Moore, 786

 subsect. *Recurvata* R. Knuth, 111  
 subsect. *Striata* (R. Knuth) Tsyren., 111  
 subsect. *Tuberosa* (Boiss.) Yeo, 649  
*abaicum* Schweinf. ex R. Knuth, 786  
*abortivum* De Not. ex Ces., 695  
*abrotanifolium* Andrews, 830  
*abrotanifolium* L. f., 830  
*absinthoides* (Willd.) Poir., 830  
*acaule* Burm. f. ex DC., 830  
*acaule* L., 830  
*acaule* Phil. ex R. Knuth, 786  
*acaule* Thunb., 830  
*acaule* Willd. ex Kunth, 469  
*acerifolium* (L'Hér.) Dum. Cours., 830  
*acerifolium* Cav., 830  
*acerifolium* Thunb., 830  
*acetosum* Dum. Cours., 830  
 var. *roseum* Dum. Cours., 830  
*acetosum* L., 830  
*acknerianum* Schur, 146  
*aconitifolium* Eichw. ex B. D. Jacks., 786  
*aconitifolium* Knaf ex Nyman, 786  
*aconitifolium* L'Hér., 124  
 [\*] *venosum* Pers., 786  
 var. *album* B. Ghosh & U.C. Bhat-tach., 152  
*acrocarphum* Ledeb., 221  
*aculeatum* Paterson ex J.F. Gmel., 830  
*aculeatum* Raeusch., 830  
**aculeolatum** Oliv., 74  
*acuminatum* Thunb., 830  
*acutibulum* Coincy, 142  
*adulterinum* Thunb., 830  
 var. *curtisii* Dum. Cours., 830  
*aedonianum* Hurrah & V. Wagh, 152  
**aequale** (Bab.) Aedo, 692  
*aequatoriale* Halfd.-Niels., 557  
*aethiopicum* Lam., 830  
*affine* Ledeb., 146  
*affine* Wight & Arn., 216  
*africanum* Cav., 830  
*agavacense* Kunth, 786  
*aionium* L. ex B.D. Jacks., 786  
*akovense* Bojer ex R. Knuth, 786  
*alatavicum* Popov ex Bobrov, 786  
**albanum** M. Bieb., 708  
**albicans** A. St.-Hil., 315  
 var. *glanduliferum* Hieron., 786

*albidum* Rydberg ex Hanks & Small, 362  
*albiflorum* Hook., 365  
 var. *incisum* Nutt. ex Torr. & A. Gray, 380  
**albiflorum** Ledeb., 111  
 f. *lilacinum* Krylov ex Bobrov, 786  
 f. *lilacinum* Krylov ex Malyshev, 786  
 var. *grandiflorum* Reverd. & Vylzan ex Gureeva & Balashova, 112  
 var. *grandiflorum* Reverd. & Vylzan., 786  
 var. *lilacinum* Krylov ex Malyshev, 786  
*alboroseum* Bomble, 753  
*album* Picard ex B.D. Jacks., 786  
*album* R. Knuth, 524  
*alceoides* Burm. f., 830  
*alchimilloides* L., 830  
*alnifolium* (Willd.) Poir., 830  
**alonsoi** Aedo, 448  
*alpestre* Chaix, 124  
*alpestre* Schur, 129, 786  
**alpicola** Loes., 422  
*alpinum* Burm. f., 830  
*alpinum* Kit. ex Kanitz, 146  
*altaicum* G. Don ex Loudon, 786  
*altaicum* Patrin, 786  
*alternans* (J.C. Wendl.) Dum. Cours., 830  
*althaeoides* L., 830  
*alticola* Schltr. ex R. Knuth, 636  
**amatolicum** Hilliard & B.L. Burt, 619  
*amethystinum* Ledeb., 688  
*amoenum* R. Knuth, 525  
*amurense* Tsyren., 221  
*anceps* (L'Hér.) Dum. Cours., 830  
**andicola** Loes., 394  
 var. *brevipedicellata* Loes., 394  
 var. *longipedicellatum* Loes., 394  
*andinum* Phil., 310  
*andrewsiana* Gower, 786  
*andrewsii* Sweet, 830  
**andringitrense** H. Perrier, 253  
*anemonifolium* L'Hér., 772  
 var. *canariense* Bolle, 776  
 var. *grandiflorum* Bolle, 786  
 var. *laevigatum* Bolle, 772  
 var. *major* Pit., 776  
 var. *minor* Pit., 776  
*anemonioides*, 786  
*anemonoides* Thunb., 830  
*angelense* Halfd.-Niels., 462  
*angelina* Nois. ex Steud., 786  
*angulatum* Curtis, 129  
*angulosum* Dum. Cours., 830  
*angulosum* Mill., 830  
*angustifolium* Gilib., 786  
*angustifolium* L'Hér. ex R. Knuth, 830  
*angustifolium* Thunb., 830  
*angustilobum* Z.M. Tan., 167  
**angustipetalum** Hilliard & B. L. Burt, 614  
*angustisectum* Engl. ex R. Knuth, 597  
*anthemifolium* (M. Bieb.) Poir., 830  
 × *antipodeum* Yeo, 799  
**antisanae** R. Knuth, 500  
**antrorsum** Carolin, 332  
*aphanoides* Thunb., 830  
*apiifolium* Andrews, 830  
*appendiculatum* L. f., 830

*apricum* Phil., 310  
**arabicum** Forssk., 255  
 subsp. **arabicum**, 256  
 subsp. **latistipulatum** (Hochst. ex A. Rich.) Kokwaro, 259  
**arachnoideum** A. St.-Hil., 105  
*arborescens* Desf., 830  
**arboresum** A. Gray, 572  
*ardens* Andrews, 830  
 var. *ardescens* Andrews, 830  
 var. *minor* Andrews, 830  
*ardescens* Andrews, 830  
**ardjunense** Zoll. & Moritz, 237  
*arduinum* L., 830  
*arenarium* Burm. f., 830  
*arenicola* Steud., 830  
*argenteum* Bory & Chaub. ex B.D. Jacks., 786  
*argenteum* Geners., 786  
**argenteum** L., 86  
 subsp. *cinereum* (Cav.) Bonnier & Layens, 76  
 var. *lucanum* N. Terracc., 88  
 var. *purpureum* Ingw., 786  
*argenteum* Lucé, 694  
*argentinum* R. Knuth, 322  
**aristatum** Freyn & Sint., 72  
*aristatum* Small, 401

## INDEX TO NEW NAMES AND COMBINATIONS

**Geranium cavanillesii** Aedo, **sp. nov.**, p. 534  
**Geranium incanum** subsp. **magniflorum** (R. Knuth) Aedo, **comb. nov.**, p. 590

CARLOS AEDO studied at the University of Oviedo, obtaining his Bachelor's degree in Biology in 1984. He received his Ph.D. from the University of Salamanca in 1994 with a thesis on the taxonomy of *Geranium subg. Erodioidea*. Since joining the *Real Jardín Botánico de Madrid* (CSIC) in 1992, he has worked in various positions and is currently Scientific Researcher since 2007. He has published widely in both scientific and popular science journals on floristics and taxonomy of vascular plants, producing more than 150 articles and contributed as author or co-author of more than 30 books. He has worked mainly on the "Flora iberica Project", which he coordinated from 2009 until its completion in 2021. He is also responsible for *Anthos*, a sister project of *Flora iberica* that has not yet been completed. During this time, he has been continually working on the taxonomy of the genus *Geranium*. This project has been developed with an initial strategy to review sections or subgenera that were well-characterized morphologically, combined with the study of species from little or poorly known areas, which have finally converged in the updated monograph of the genus presented here.
